**MONTEYOR (or MONTEMOR), JORGE (1520?–1561)**, Spanish novelist and poet, of Portuguese descent, was born about 1520 at Jerez de la Frontera, but his name was derived from the Spanish form of which he is sometimes called Jorge de la Cerda. He seems to have studied music in his youth, and to have gone to Spain in 1543 as chorister in the suite of the Portuguese Infanta Maria, first wife of Philip II. In 1552 he went back to Portugal in the suite of the Infanta Juana, wife of D. Joao, and on the death of this prince in 1554 returned to Spain. He is said to have served in the army, to have accompanied Philip II. to England in 1555, and to have travelled in Italy and the Low Countries; but it is certain that his poetical works were published at Antwerp in 1554, and again in 1558. His reputation is based on a prose work, the <i>Diana</i>, a pastoral romance published about 1559. Shortly afterwards Montemor was killed in Piedmont, apparently in a love affair; a late edition of the <i>Diana</i> gives the exact date of his death as the 26th of February 1561. The <i>Diana</i> is generally stated to have been printed at Valencia in 1542; but, as the <i>Canto de Orfeo</i> refers to the widowhood of the Infanta Juana in 1554, the book must be of later date. It is an importation of the Italian satirical pastoral, as the starting-point of a universal literary fashion; and as the indirect source, through the translation included in Googe’s <i>Elogios, epitaphes and sonnets</i> (1563), of an episode in the Two Gentlemen of Verona. Though Portuguese was Montemor’s native language, he only used it for two songs and a short prose passage in the sixth book of the <i>Diana</i>. His mastery of Spanish is amazing, and even Cervantes, who judges the verses in the <i>Diana</i> with unaccustomed severity, recognizes the remarkable merit of Montemor’s prose style. That he pleased his own generation is proved by the seventeen editions and two continuations of the <i>Diana</i> published in the 17th century, by parodies, imitations and renderings in French and English.

**MONTENEGRO**, a country of south-eastern Europe, forming an independent kingdom situated upon the western side of the Balkan Peninsula, and possessing a small coast-line on the Adriatic Sea. The name is the Venetian variant of the Italian <i>Monte Nero</i>, and together with the Albanian <i>Mal Esyia</i>, the Turkish <i>Kara-dagh</i>, and the Greek <i>Mauro Vouno</i>, reproduces the native, or Serb, <i>Tarngora</i>, “the Black Mountain”; it is derived from the dark appearance of Mount Lovchen, the culminating summit of Montenegro proper, of which the northern and eastern declivities, those which are viewed from the country itself, are in shadow for the greater part of the day. The dusky pine forests, which once clothed the mountains and of which remnants exist on its northern slope, contributed to its sombre aspect. Up to the end of the 15th century, when its territory became restricted to the mountainous districts immediately north and east of Mount Lovchen, the kingdom was known as the <i>Zenta or Zeta</i>, but the name Tarngora was probably used locally in this region from the time of the earliest Slavonic settlements.

Montenegro extends between 41° 55' and 43° 21' N., and between 18° 30' and 20° E.; its greatest length from north to south is about 100 m.; its greatest breadth from east to west about 80 m. It is bounded by the Adriatic on the S., the seaboard extending for 28 m.; by the Primorje, a strip of the Dalmatian littoral, on the S.W. and W.; and by the Austrian (formerly Turkish) provinces of **Litoral and Boundaries.**

1 Cf. the similarly-named <i>Tarna Planina</i> in eastern Montenegro, Tcherki Vrhh, the culminating summit of Mount Vitosh in Bulgaria, and <i>Mavo Youno</i> in the island of Salamis. Various other explanations of the name Montenegro, mostly of a fanciful character, have been put forward: see Kurt Hassert, “Der Name Montenegro” in <i>Globus</i>, No. 67, pp. 111-113 (Leipzig, 1895).
of Bosnia and Herzegovna on the N.W. and N.; by the Ottoman empire both in the sanjak of Novibazar, on the N. and N.E., and also in the vilayets of Kossovo and Scutari on the N.E., E., and S.E. Its area, as officially estimated after the treaty of Berlin had been enforced in 1880, amounts to 3255 sq. m., or considerably less than half the size of Wales. The present frontier, which was not finally delimited till 1884, ascends the Boyana river from its mouth as far as Lake Sass (Shas), then follows the river Megured to the summit of Mount Bratovitza, reaching Lake Scutari at a spot opposite the island of Goritza Topal. Crossing the lake north-east to a point a little south-east of Plavitzka, and leaving the territory of the HHot and Klementi tribes to the south, and the districts of Kutchka Kraina to the north, it passes north of the districts of Plava and Gusine and reaches the western end of the Mokra Planina, where it turns to the north-west. After crossing the Lim at its junction with the Skula, it coincides with the old frontier for some distance; then reaching the Tara at Malakovatz, it follows the course of that river to its junction with the Piva: turning southwards, it reaches the old frontier once more at Klobuk, and, passing between the district of Gravovo and the Krivoshan Mountains, approaches to within a few miles of the Bokche of Cattaro: then, following the maritime mountain ridges for a considerable distance, it rejoins the coast a little south of Spizza.

Physical Features. — Montenegro, which forms the meeting-point of the Balkan, Pannonian, and Alpine ranges, seems at first a mere chaos of mountains. It is, however, naturally divided into three parts, each with its own character. (1) Fertile and well-watered plains, not unlike those of Lombardy, border the river Zeta, and after its junction with the Moracha, extend along the course of that river to Lake Scutari. A fringe of small lakes forms the maritime plain extending between the Sutorman range and the mouth of the Boyana. (2) Westward, under the shadow of Lovchen, is the Katunska, or Shepherds' Huts, the cradle of Montenegro. The table-land is traversed by a line of barren, calcined, and with strata sinking to the south-west at an angle of often 20°. The rocks have been split by atmospheric agencies into huge prismatic blocks, and the cracks have been gradually worn into fissures and ravines. The south-west side of the interior of the stony mass is hollowed out into galleries and caves, some of great length; during the rainy season subterranean landslips frequently produce local earthquakes, extending over an area of 10 or 12 ft. The entire land surface and drainage is practically the only cultivated districts in this region. (3) Over the entire north stretch the massive mountain chains which link the Herzegovinan Alps to those of Albania, the scenery recalling that of the Apennines. (4) The mountains of the north-western part are wooded tracts extending north of Nikshitch to the Dormitor mountain group. The Dormitor district contains rich grassy uplands dotted with numerous small lakes, from which it derives its name of 'lake country'; the Tara and Piva flow through magnificent gorges clothed with rich forests, and unite near the extreme north of the frontier. On the north-east are the high rounded Brda Mountains, covered with virgin forest or Alpine pastures, and broken here and there by jagged dolomite peaks. In the district of the Vasovetchi, which surrounds the little town of Andriyevice, is the fine double peak of Kom, and, a little to the south-west, the summit of Maglitz, commanding a magnificent view to Lake Scutari and the Sutorman range in Albania. The contrast between the rich undulating land to the south of the northern regions and the sterile calcined rocks of Montenegro proper is very remarkable.

The Montenegro mountain system is divided into four masses: (1) the north-western, formed by the Tara and Piva rivers with Dormitor, one of the highest mountains in the peninsula (9140 ft.), Yablonov Vrkh (7113 ft.), and the Vrkhove Pochorat (6601 ft.); (2) the group between the Zeta and the Moracha, the valley of Gusa and of Cetigne and its tributaries, the north-eastern mass (6860 ft.). (8) the group between the Moracha and Tara with Stoj (7323 ft.) and Gradiste (7155 ft.); and (4) those between the upper Tara and the upper Lim (4168 ft.), Val Tivol, 766 ft. on the frontier. In Montenegro proper the only large lake is Lovchen (6563 ft.), between Cetigne and the western frontier. Between Lake Scutari and the sea is the Sutorman range with the fine pyramidal summit of Rumija (5148 ft.).

1 This must be distinguished from the higher Maglitz (7999 ft.), on the northern frontier, near the junction of the rivers Tara and Piva.

2 Overhanging Antvari. The prevailing formations of the north and east are Palaeozoic sandstones and schists, with underlying trap. Throughout Montenegro have been identified: (1) Palaeozoic schists, (2) Wirfen strata of Lower Trias, (3) Trap of the Palaeozoic and Wirfen strata, (4) Triassic limestone, (5) Jurassic limestone, (6) Cretaceous limestone, (7) Flysch, in part certainly Eocene, (8) Neogen or younger Tertiary formations. The watershed between the Adriatic and the Black sea crosses the country from west to east in a very irregular line, the southern districts being drained by the Zeta-Moracha river system, which finds its way to the Adriatic by Lake Scutari and the Boyana, while the streams from the northern districts form the headwaters of the Drina, which reaches the Danube by way of the Save. The Zeta, rising in Lake Stano, near Nikshitch, is remarkable for its subterranean passage beneath a mountain range 1000 ft. high. At Ponor, not far from that town, the water vanishes in a deep chasm, reappearing at a distance of several miles on the other side of the mountains. Its whole course to its junction with the Moracha is about 30 m. Rising in the Vavorye Planina, the Morachat sweeps through mountain gorges till it reaches the plain of Podgoritsa; then for a space it almost disappears among the pebbles and other alluvial deposits, nor does it again show a current of any considerable volume till it approaches Lake Scutari. In the neighbourhood of Lukel and Leskopolye it flows through a precipitous ravine from 50 to 100 ft. high. In the dry season it is navigable from the lake to Zhablak. The whole course is about 60 m. Of the left-hand tributaries of the Morachat the Sen or Izen deserves to be mentioned for the magnificent canyons through which it flows between Most Tamarau and Dinosa. On the one side rise the mountains of the Kutchi territory on the other the immense flanks of the Prokleta range, the walls of the gorge vary from 1200 to 4000 ft. of vertical height. Lower down the stream the rocky banks approach so closely that it is possible to leap across without trouble. The Sems rises in northern Albania, and has a length of 70 m. The Rieka or the Tivol. In the upper part of the middle course of the Sen, there is an immense cave south-east of Cetigne and falls into Lake Scutari. The three tributaries of the Drina which belong in part to Montenegro are the Piva, the Tara, and the Lim, respectively 55, 95 and 140 m. in length. The Tara forms the northern boundary of the kingdom for more than 50 m., but the Lim flows beyond the border after the first 30 m. of its course. The western half of Lake Scutari, or Skodra, belongs to Montenegro;

3 Dulke is the name still borne by the ruins of the Roman Dioeclea, often, but wrongly, written Dioeclea, from its association with the Emperor Diocletian.
MONTENEGRO

left after rain in the crevices of the rocks, and one may see harvests only a few yards square. The vineyards produce excellent grapes, but wine production, which might become an important industry, is at present limited to home consumption. Tobacco is largely cultivated, especially in the neighbourhood of Podgorica; the annual production is estimated at 3,000 lb. Stock-raising is more largely carried on than agriculture. In the north districts of the bee woods; goats and large flocks of sheep, celebrated for their thick fleeces, thrive on the high pastures, and the lower districts support a large amount of cattle. Among the native breeds of cattle is small, but among other efforts to improve it, a stock-farm is maintained by Prince Nicholas at Niksich. The horses, as elsewhere in the Balkan Peninsula, are diminutive, with poor manes and tails. A few in the Kutchi districts, and mulebrows are grown for silkworms.

Commerce and Industries.—The exports, valued at £80,265 in 1906, include cattle (large and small), smoked and salted meat known as boeuf charcuté, fish, fish-salting, flour, hemp, hay, tobacco, silk, and silk-thread. The imports, valued in the same year at £239,505, consist mainly of manufactured articles, such as iron utensils and weapons, soap, candles, &c., and colonial products. In 1904, when Montenegro renounced its commercial treaties, the old custom duties were abolished on the grounds that in 1906 the imports had been decreased by 25%. This caused much discontent among the people, who had been having steadily poorer since 1900; and many families emigrated. The exportation of cattle is greatly hindered by the high tariff imposing on them an entry of £11 per head. The same thing applies to the silk industry. There are practically no manufactures: the men disdain industrial employment, while the women are occupied by household duties or work in the fields. A brewery and a cloth factory, however, have been established at Niksich. A herring fishery is worked at Cetinje, and there is an olive-oil refinery at Antivari. The coarser cloth worn by the peasants is home-made; the finer kind worn by the wealthier class is imported.

Communications.—The progress of trade and the development of the natural resources of the country must largely depend on improved means of communication. In this direction considerable progress has already been achieved. Montenegro possessed in 1907 229 m. of excellent carriage roads, admirably engineered and maintained. But during the years 1899 to 1906, the line of the Zeta river from Cetinje to Niksich was improved; in 1907, it was afterwards prolonged to Podgorica, Danilovgrad, and Niksich. Another road connects Podgorica with its port, Plavina, on Lake Scutari; a third one, from Antivari to Cetinje, and unites the sea-coasts with the richest districts of the interior. The ports of Antivari and Dulcigno are insuffi ciently sheltered, but are capable of considerable improve ment. The navigation of the Zeta river was opened up by the British government through the Prince of Antivari by the Italian-Montenegrin Compagnia d’Antivari, which in the same year began the construction of a railway from that port to Virbazar on Lake Scutari. Four steamers belonging to the same company, besides other small steamers, are employed on the line and the regular service between Antivari and Bar on the Italian coast is maintained by the “Puglia” Steamship Company. The Cetinje is navigable by sea-going vessels as far as Oboti (125 m. from its mouth), where a cargo from Cetinje must be transferred to small river steamers. In 1905, 431 steamers were employed on the line for this purpose. There were in 1905, 16 post offices and 20 telegraph stations, with 412 miles of wire. The number of letters posted in that year was 91,750. The telegraph is much used by the people: the number of telegrams sent in 1906 was 54,750.

Population.—In 1882 the population of Montenegro was estimated as low as 160,000 by Schwartz. A modern estimate is 250,000. According however, to information officially furnished at Cetinje, the total number of inhabitants in 1900 was 311,564, of whom 293,527 belonged to the Orthodox Church; 12,493 were Moslems and 5,554 were Roman Catholics; 71,528, or 23%, were literate and 240,036, or 77%, were illiterate. The total number in 1907 was officially given as 382,000. The population is densest in the fertile eastern districts; Montenegro proper is sparsely inhabited. Emigration is greatly increasing, especially to America; the number of emigrants is given as 6674 in 1905 and 4,436 in 1906. The bulk of the inhabitants belongs to the Serbo-Croatian branch of the Slavonic race. There were about 5,000 Albanians resident in the country in 1900, besides a small colony of gipsies, numbering about 800, a few of whom had abandoned their nomadic life and settled on the soil. The Moslems, whose thrift and industry have won encouragement from the Crown, greatly decreased for some years after 1880 owing to emigration. The capital of Montenegro is Cetinje (3,000 inhabitants in 1900, 5,138 in 1907). The chief commercial centres are Podgorica (13,347) and Niksich (6872), with the ports of Antivari (2777) and Dulcigno (5166). These towns are described under separate headings. Danilovgrad (1226) on the

Flora and Fauna.—The Alpine vegetation of the mountains gives way to pine forests in the sub-Alpine zone (about 6000 ft.); below these the beech, and then the oak, the walnut, the wild pear, and wild plum make their appearance; the fig-tree, the mulberry, and the vine were also found. The orange, laurel and olive in the lower Moracha region, and more abundantly in the Zeta and Scutari districts. In the forest districts the beech is the prevailing tree up to about 4500 ft. The chestnut forms little groves in the country between the sea and Lake Scutari but never ascend more than 1000 ft. Pomegranate bushes grow wild, and in many parts of the south cover the foot of the hills with dense thickets, the crimson blossoms being a striking feature of the scene. The more rare and valuable is the oak, which is a favourite beverage with the people. Bears are still found in the higher forests; wolves, and especially foxes, over a much wider area. A few chamois still roam on the loftiest summits, the moose, and in some places, the reindeer, are met with in the same district, and the hare is abundant wherever the ground is covered with herbage. There are one or two species of snakes in the country, including the poisonous Illyrian viper (Vipera ammodytes). Esculent frogs, tree frogs, the common tortoise, and various kinds of lizards are all common. Scorpions and numerous reptiles infest the arid rocks of the Katunska. The list of birds includes golden eagles and vultures, twelve species of falcons, owls, hoopoes, partridges, herons, pelicans, ducks (ten species), nightjars, &c. Immense flocks of water-fowl haunt the upper reaches of Lake Scutari. The rivers abound with trout, tench, carp and eels; the trout of the Moracha is especially esteemed for its taste. The most important economic product is the fish oil, which is obtained from the scomber (Scomber alburnus), a kind of sardine, which supplies an article of food and merchandise to a considerable portion of the population. The fish, which enter the Rieka inlet of Lake Scutari during the winter, are trawled at a few points with great success. The fishing season is inaugurated with a religious service; they are salted and exported in large quantities to Trieste and the Dalmatian coast. The annual take is valued at £4000. The sea-fisheries are of less value. The total produce of the fishing industry, which is a coal are said to exist; there is a natural petroleum spring in the neighbourhood of Virbazar. Agriculture and Stock-farming.—Except in the lowlands, which serve as the granaries of the country and are covered with wheat, barley, rye, and oats, the cultivation of vegetables is not various; there is little tillage. Methods and implements are alike primitive. In the Katunska the peasants are glad to enclose the smallest spaces of the fertile red soil which is

The name Brda (literally "mountains") signifies in ordinary speech the mountain-group east of the Zeta which was incorporated in the principality in 1796. It figures in the prince’s title, but is not otherwise used in official documents.
Zeta was founded in 1873 by Prince Nicholas and named after his predecessor, Danilo II. It is the vicar in Oriška, the part of Zeta that takes great authority in personal, Spuzocht. The little lower on the east bank of the Zeta, possesses a fortified acropolis. Niegush or Nyegush (1853), on the road from Cettigne to Cattaro, is the ancestral abode of the ruling family, which originally came from Niegush in Herzegovina. Zhablik (1200), near Lake Scutari, was the capital until late in the 15th century. It was a Venetian stronghold. Rieka (1768), near the northern end of Lake Scutari, derives some commercial importance from its position. Grahowo (1900), in the extreme west, is famous for the Turkish defeats of 1851 and 1876. Other small towns are Kolashin, Vibarzor and Andrijevitz.

The Montenegrins present all the characteristics of a primitive race as yet but little affected by modern civilization. Society National Character- is regarded as the highest virtue, and warlike prowess constitutes the principal, if not the only, claim to pre-eminence. The chiefs are distinguished by the splendour of their arms and the richness of their costume; women occupy a subject position. The physically strong and often adopt the distinction of minstrels and sing the exploits of their countrymen like the bards of the Homeric age. A race of warriors, the Montenegrins are brave, proud, chivalrous and patriotic; on the other hand, they are vain, lazy, cruel and revengeful. They possess the domestic virtues of sobriety, chastity and frugality, and are well-mannered, affable and hospitable, though somewhat contemptuous of strangers. They are endowed in no small degree with the high-fbown poetic temperament of the Serb race, and delight in interminable recitations of their martial deeds, which are sung to the strains of the giska, a rudimentary one-stringed fiddle. Dancing is a favourite pastime. Two characteristic forms are the slow and stately ring-dance (kolo), in which women sometimes participate, though it is usually performed by a circle of men; and the livelier measure for both sexes (oro), in which the couples face one another, leaping high into the air, while each man encourages his partner by rapid revolver-firing. The oro is the traditional dance in the Katunaska district. Wild dances, generally improvised, over the dead; mourners try to excel one another in demonstrations of grief; and funerals are celebrated by an orgy very like an Irish “wake.” Like most imaginative peoples, the Montenegrins are extremely superstitious, and belief in the vampire, demons and fairies is almost universal. Among the mountains they can converse fluently at astonishing distances. The physical type contrasts with that of the northern Serbs; the features are more pronounced, the hair is darker, and the stature is greater. The men are tall, often exceeding 6 ft. in height, muscular, and wonderfully active, displaying a cat-like elasticity of movement when scaling their native rocks; their bearing is soldier-like and manly, though somewhat theatrical. The women, though frequently beautiful in youth, age rapidly, and are short and stunted, though strong, owing to the drudgery imposed on them from childhood; they work in the fields, carry heavy burdens, and are generally treated as inferior beings. Like the Albanians, the Montenegrins possess an extraordinary vitality. They are very fond of demonstrations of physical strength, and men wear a red waistcoat, embroidered with gold or black braid, over which a long plaid is sometimes thrown in cold weather; a red girdle, in the folds of which pistols and yataghans are placed; loose dark-blue breeches and white stockings, which are generally covered with gaiters. The opanka, a raw-hide sandal, is worn instead of boots; patent leather long boots are sometimes worn by military officers and a few of the wealthier class. The headdress is a small cap (kapa), black at the sides, in mourning for Kossovo; red at the top, it is said, in token of the blood shed then and afterwards. On the top near the side, five semicircular bars of gold braid, enclosing the king’s initials, are supposed to represent the five centuries of Montenegrin liberty. There

is little authority, however, for this and other fanciful interpretations of the pattern, which was adopted in the reign of Peter I; the red fer, from which the kapa probably derives its colour, was previously worn. A blue or green mantle is sometimes worn in addition by the chiefs. The poorer mountaineers are often dressed in coarse sacking, but all without exception carry arms. The women, as befits their servile condition, are generally clothed in black, and wear a black head-dress or veil; on Sundays and holidays, however, a white embroidered bodice, silver girdle, and bright silk skirt are worn beneath an open coat. Over this is placed a short, sleeveless jacket of red, blue, or violet velvet, according to the wearer’s age. Unmarried girls are allowed to wear the red kapa, but without the embroidered badge. The Vasoевич tribe retain the Albanian costume, in which white predominates. Turkish dress is often seen at Antivar, Dulcigro and Podgoritz. The dwelling-houses are invariably of stone, except in the eastern districts, where wooden huts are found. As a rule, only the mansions of cattle-owners have a second storey: the ground floor, which is dark and unventilated, is occupied by the animals; the upper chambers, in which the family reside, are reached by a ladder or stone staircase. Fire-places are rare, and the smoke of the fireplace escapes through the windows (if any exist) or the open doorway. The principal food of the people is rye or maize cake, cheese, potatoes and salted scorana; their drink is water or sour milk; meat is seldom tasted, except on festive occasions, when raki and red wine are also enjoyed. The Montenegrins are great smokers, especially of cigarettes; in the districts which formerly belonged to Turkey the men, whose dignity never permits them to carry burdens, may be seen going to market with the chibik, or long pipe, slung across their backs. The mother possesses little influence over her sons, who are trained from their earliest infancy to cultivate warlike pursuits and to despise the weaker sex. Betrothals often take place in early childhood. Young men who are attached to each other are accustomed to swear eternal brotherhood (pobratimstvo); the bond, which receives the sanction of the Church, is never dissolved. Marriages between Montenegrins and Albanians are common, and are often arranged by the parents. The sadruga, or house-community, under the rule of a streshina, or house-father, is found in Montenegro as in other Slavonic lands (see Servia). The tribal system still exists, but possesses less significance than in Albania, owing to the centralization of authority at Cettigne. The tribe (pleme, pl. pliema) is subdivided into clans (bratstva).

Constitution and Government.—Notwithstanding the creation of an elective senate in 1831, the grant of a so-called constitution in 1868, and the establishment of a responsible ministry in 1874, the government remained autocratic till 1905, the whole power, even the control of religion and finance, which the constitution of 1868 had conceded to the senate, being centred in the hands of the prince, who in 1910 assumed the title of king. The senate, instituted by Peter II. with the object of limiting the power of the tribal chieftains, was in 1881 merged in a council of state, the members of which, six in number, were nominated and dismissed by the prince. The council supervises measures to be laid before the Skupština, or national assembly, and exercises a disciplinary control over officials. The ministry comprises six departments: (1) the interior, with separate sections for public works, posts and telegraphs, commerce and industry, shipping, sanitary service and agriculture; (2) foreign affairs; (3) war; (4) finance; (5) justice; and (6) education. On the 10th of December 1905 a new constitution was proclaimed by Prince Nicholas. A Skupština was instituted, consisting of 62 elected deputies, 9 ex officio members (the higher ecclesiastical and civil dignitaries), and 3 generals nominated by the prince. The Skupština is elected by manhood suffrage for a period of four years, and is summoned annually on the 31st of October. In conjunction with the Crown it exercises the legislative power; the ministers are responsible to it as well as to the Crown. The constitution affords financial supervision to the Skupština, which elects a board of control and votes an annual budget; it guarantees liberty of the person, of religious belief, and of the

1 The ring-dance, known as the kolo (literally, "wheel") in all Serb countries, corresponds with the Bulgarian koru (to be distinguished from the Montenegrin oro), and is almost universal throughout the Balkan Peninsula; it is seldom, however, danced in the rocky Katunaska district, where level spaces are rare.

MONTENEGRO 769
press, together with the right of public meeting, and abolishes the death penalty for political offences.

**Administration and Justice.**—For purposes of local administration the country is divided into 5 departments (oblasti), each governed by a prefect (spravitelj), and 66 districts (kapetanati), each under an official styled kapetan. The prefects and kaptetans are nominated by the king on the recommendation of the minister of the interior. Rural communes, each under an elected kmet, or mayor, exist in Montenegro as in all Slavonic countries. The kmets act as justices of the peace, and there is an appeal from their decisions to the courts of first instance (kapetanski sudove), of which there is one in each district, the kapetan acting as judge. In each of the five departments there is a superior court (oblasni sud), with a president and two judges; at Cettigne there is a high court of justice (veliki sud), which is the final court of appeal. The ultimate appeal to the prince was abolished in 1902, when Prince Nicholas laid aside his judicial functions, retaining only the prerogative of pardon. The judges, who are removable, are nominated by the king on the recommendation of the minister of justice. With a single exception there are no professional advocates in Montenegro; each man is his own counsel, bringing his own witnesses. The local gendarmerie, numbering 150 men, is distributed in the five departments. The kapetanati have replaced the former local divisions, the pristini sudovi, each of which had a judicium, and there is one or more of the bratstva. The codification of the law, which had previously been administered according to unwritten custom, was first undertaken by Peter I. in 1796. An improved code, issued by Danilo II. in 1855, still contains many quaint enactments. The excellent code drawn up by Professor Bogishitch, a native of Ragusa, in 1888, was revised and enlarged in 1890. It contains elements from various foreign systems scientifically adapted to national usages and requirements. A large number of judicial reforms were carried out by Count Voïnovitch, who succeeded Professor Bogishitch in 1899; in 1905 a new code of civil procedure was promulgated, and a criminal code in the following year. The only prison is at Podgoritsa. In the old prison at Cettigne, closed after 1902, many of the inmates were free to walk in and out at pleasure. Some were burdened with fetters, rather as a punishment than for restraint. Until the completion of an asylum in 1905, dangerous lunatics were confined in prison. The commonest offences are murder and robbery; despite vigorous measures taken by the king and his predecessors, the blood-feud, or vendetta, cannot be stamped out, being approved, and even encouraged, by the commerce. Only in exceptional cases is the duty of avenging their next-of-kin; they have been known, however, to undertake it, disguising themselves in male attire. A man who kills his slanderer, or otherwise avenges his honour, often receives a nominal term of imprisonment. Robbery, if practised by means of raids across the frontier, is popularly regarded as a venal offence. Other forms of crime are rare, and foreigners may traverse all parts of the kingdom, except the neighbourhood of the Albanian border, in perfect safety. The death penalty was first introduced by Peter I. Executions are carried out by a firing party selected from the various tribes, in order to prevent the relatives of the criminal from exacting vengeance. Exceptional severity is shown in the treatment of political offenders, who in some instances have been subjected to solitary confinement for years without trial.

**Finance.**—Financial statistics are not published. The total receipts were estimated in 1907 at 2,773,660 Austrian krones, the principal sources of income being the taxes on land, houses and cattle, the monopolies of tobacco, salt, petroleum and alcohol, and the customs dues. The total expenditure was estimated at 2,763,994 krones, the principal items being: civil list, &c., 189,866 krones, ministry of interior, 574,822 krones; of foreign affairs, 144,547 krones, of justice, 232,710 krones; of finance, 502,651 krones; war, 113,696 krones; of education, 269,268 krones; of administration, 244,500 krones. The public debt is under 300,000. The contribution of Montenegro to the Ottoman debt has not been fixed. From time to time considerable subventions have been received from Russia and Austria. The annual Russian subsidy, mainly for military and educational purposes, is stated to be about £40,000. Montenegro has no mint; Austrian paper money and coins are generally employed together with Montenegro nickel and bronze. This coin, struck in Austria, Turkish gold and silver are also in circulation. The former Turkish and Venetian weights and measures have been superseded by the French.

**Defence.**—The Montenegrin is a born warrior; his weapons, which he lays aside, are his most precious possession, and distinction in battle is the sole mark of social or political rank. All young men have at some time or other learned the use of a revolver in the kolon or waistband. "You might as well take from me my brother as my rifle," says a native proverb; and rifles are almost universally carried near the Albanian frontier, whether they be trenching or camping, for they are an excellent weapon against the Turks. The Turks, with their revenue and national resources, have been shown to be extremely efficient at the same time. The Montenegrins are frequently, when in large numbers, a match for the Turks, even when the latter are under the influence of brandy and wine; but in small parties they are no match for them, and have often been severely beaten and harangued by rifle-fire; then the mountaineers, throwing aside their firearms, deliver a swift attack with the hanjar, or yataghan, which they wield with terrific effect. A number of heads cut off in battle adorns this parasol of a small tower outside Cettigne, called the "Turks' Tower," as late as 1856. When reduced to extremity the Montenegrins often committed suicide rather than fall into the hands of the enemy, the last cartridge being reserved for this purpose; disinclined cowards who could not be removed used to be beheaded, in 1876 to prevent their escape. After the Turkish war for independence, a Russian officer who was wounded at Klubuk. Savage methods of warfare, however, have been strongly disavowed by King Nicholas and his predecessor. Till the middle of the 19th century the territories of Montenegro (the principality of SU), together with a number of other tribesmen under local chiefs, whose rivalries often proved injurious to the national cause. The supreme command, however, always rested with the prince. The nucleus of a permanent corps was created by Prince Nicholas in 1904. His brother, Peter II., is known as kruna, from the feathers (pere) which adorned their caps. The name is still borne by a small corps (20 men in 1907) which guards the residences of the king and his sons, but the feathers are now replaced by red cloth. There are 4,782 permanent military personnel capable of bearing arms, and instituted a military hierarchy of voivodes (generals), sirdars (colonels) and kapetans; the organization, which was based on the tribal system, was remodelled by the former officers of the principality, who thought the kruna to receive military instruction. In the same year a new system of precision was introduced: the cost and complex structure of the new weapons threatened to cause serious difficulty, but Russian aid was soon forthcoming. Since 1879, though arms and ammunition are manufactured on a small scale in the capital, they are mainly supplied from without. In 1895 the tsar presented Prince Nicholas with 30,000 Berdan rifles, besides ordnance and other war material, and in 1908 sent a further gift of 55,000 Moskovskie rifles. Every able-bodied man may be called upon to serve on a temporary basis, and any person capable of bearing arms, and serving in the militia, may, if needed, be exempted from payment of a capitaf tax. The military organization has undergone a gradual transformation since the year 1870, when the old" kruna, as well as the kruna, is gradually being replaced by the officer corps. Both standing and volunteer forces are enrolled, the former being maintained on an annually renewed footing, the latter being subject to conscription. When the military schools were founded, in 1837, at Nikshitch and Podgoritsa, they were purely for officers. In 1897, when a military school was founded at Tivat for the training of the territorial troops, the new course was organized. The only schools of this kind are those at Nikshitch and at Podgoritsa, and the discipline of the army is not a perfect one. The war strength is estimated at 58,000 to 42,000 men, the infantry being composed of about 32,000 men of the first ban of and 20,000 of the second ban, which would be made up by conscription. The artillery of about 1,000. Considerable deduction must be made from these numbers in view of the emigration of recent years; according to some authorities between 20,000 and 30,000 emigrated to America and other countries outside. It is expected, however, that many of these would return should the country become involved in war. The infantry is divided into 11 brigades, each containing from 4 to 6 battalions; the total number of battalions is 50. The army is composed of a varying number of tchete, or companies, each of which belongs to a separate clan and has its own bairakatar, or standard-bearer. The younger men of the first ban are occasionally exercised in the neighbourhood of their homes on Sundays and holidays. They are armed with the Moskovka (repeating) rifle, but a Berdan rifle is
also kept in each household. The artillery was composed in 1910 of 18 siege guns, 12 field guns, 36 machine guns, with 4 howitzers, 15 mortars and 18 machine-guns (6 Gatling and 12 Maxim-Nordenfeld); the principal arsenal is at Spuz, where the heavier guns are kept, the others are distributed among 8 of the 11 local brigades. The 18 serbs, whose numbers were increased by Prince Danilo, were disarmed in 1898, when steps were taken to form a bodyguard of 3000 picked men under Prince Mirko, King Nicholas's second son, but the project was abandoned as a result of the general movement of the Montenegrin army. In 1898, the whole population of the country was not more than 200,000. Owing to the lack of open country there is no cavalry. In 1894 the sultan presented Prince Nicholas with equipment for a small mounted body-guard (32 men), and offered the services of three instructors. This corps, however, ceased to exist in 1899 after the Montenegrin army was increased by 18,000 men. A field and mountain ambulance corps has been formed. Transport is deficient, all draught animals, however, in the country have been registered and a few carts have been provided. The wives and daughters of the troops provide the commissariat, and carry the ammunition.

Religion. The Montenegrin Church is an autochthonous branch of the Eastern Orthodox communion. In 1894 it formally vindicated its independence against the claims of the Russian synod. The church is the most revered and respected institution of the nation. The theocratic system of government which existed from 1516 to 1851 tended to unite the patriotic and the religious instincts of the people. Since the separation of the spiritual and temporal powers in 1851, the see of Cettigne, in which the diocese of Ostrog is included, has become essentially an episcopal see of the Orthodox Church, and possesses a nominal jurisdiction over Scutari and the Primorje. In judgments relative to divorce, the court may be reversed by the king. Otherwise he is supreme in matters spiritual. There are 10 archdeacons and 100 parish priests, and a college of 10 bishops and priests, the chief of which is the metropolitan, who is elected by the council of the church and ordained by the metropolitan. Besides the metropolitan, 10 archdeacons are appointed by the metropolitan and ordained by the council, and there are 10 bishops in the diocese of Ostrog, 10 in the diocese of Cettigne, and 10 in the diocese of Scutari. The churches are small and unperturbing structures, almost all exactly alike; a handsome cathedral, however, has been built at Scutari. The parish church of Cettigne is remarkable for its size, and has a golden dome. The buildings are vaulted and are covered with frescoes, and are decorated with inscriptions, which exist at Ostrog, Cettigne, and in the principal towns of the country. The church is the most ancient institution in the country, and the most numerous and important are the extensive ruins of Danilovo, known as Dukelé, the birthplace of the Emperor Dioclétian. The city, which received the franchise under the Flavian emperors, occupied a remarkable site at the junction of the rivers Zeta and Moracha. The outer walls are still preserved, and many inscriptions carried out in 1893 by M. Rovinski and Messrs J. A. R. Munro, Milne and Anderson reveal a considerable portion of the ground-plan, including several streets and a forum. Around the buildings in the town were the ruins of four temples, of which two were temples, one a Christian basilica, and a later church; the other inscriptions, columns, richly worked capitals, and tracery, and mosaics have been brought to light. At Medun and Dukelé are found inscriptions in Latin letters and Byzantine arts are found in parts of the town. The ravages of the Turks obliterated almost every trace of medieval culture. The fortress of Obod, the site of the famous printing-press, is a heap of ruins; a fragment of the old press has been preserved, and is exhibited in the museum of the town of Herceg-Novi. The building, the home of the reigning vladikas, had been previously sacked by the Turks in 1523, and was again destroyed by them in 1714. In the fortress-monastery of Sank Nicholas (founded in 1252), and in the priory of the Moracha, are some interesting and well-preserved frescoes which date from the 13th century. The monastery of Ostrog, about twelve miles from Nikšić, is a comparatively recent foundation, dating from the 18th century. It has been styled the "Lourdes of the Balkans," owing to its reputation as a place of pilgrimage for the Montenegrins and other Orthodox pilgrims, and even by Roman Catholics and Moslems. The upper portion, situated in the cliff of a precipitous rock, was in 1768 and again in 1862 successfully defended by a handful of men against the Turks.

History. The history of Montenegro as an independent state begins with the battle of Kosovo (1389), but the country had enjoyed periods of independence or semi-independence at various epochs before that event. It formed a portion of the district of Pravešilatina in the Roman province of Dalmatia on the borderland of the two empires of the West and East; it alternately shared the fortunes of either till the close of the 5th century. It was then conquered by the Ostrogoths (A.D. 493), but half a century later definitely passed under Byzantine rule, having already acknowledged the ecclesiastical authority of Constantinople, a circumstance which determined the course of its subsequent history. Illyria and Dalmatia succumbed to the great Serbian-Croat invasion of the 6th and 7th centuries; the Serb race by which Montenegro is now inhabited occupied the country about the middle of the 7th century. A confederacy of Serb states was formed under župans, or feudal princes, dependent on the grand župan, who was nominally the vassal of the Greek emperor. The Serb principality of the Zeta, or Zent, originally included the Herzegovina, Cattaro and Scutari, as well as the Montenegrin of to-day, and was ruled by a župan resident at Dociela. The principality, though retaining its župans, was practically united with the Serbian kingdom between 1759 and 1766 under the Neumans' dynasty, which sprung from Dociela. After the death of the great Serb Tsar Dusan in 1356 the feudatory princes of his empire became more or less independent, and the powerful family of Balša established a dynasty in the Zeta, eventually transferring its capital from Dociela to Scutari.
After the fatal defeat of Kossovo, which extinguished the independence of Servia for more than four centuries (see Servia), George Balsha, the ruling prince of the Zeta, withdrew to the mountainous portion of his realm, which became an asylum for many of the Servian nobles and for others who had been outlawed or persecuted by the Turkish conqueror. The principality now owned no suzerain, and the history of its heroic struggle with the Turks began. The long record of warfare is varied by conflicts with the Venetians, who at times allied themselves with the mountaineers, but usually deserted them in the hour of need. The Balsha family became extinct in 1421, and a new dynasty was founded by Stephan Tzernoyevitch, or Tzernovitch, who fixed his capital at Zhabliak on the north-east side of Lake Scutari, and joined with his relative, the famous Scanderbeg (q.v.) in many campaigns against the Turks. After the Turkish conquest of Bosnia in 1463, of the Herzegovina in 1476 and of Albania in 1478, and the surrender of Scutari by the Venetians in 1479, the Montenegrins found themselves surrounded on all sides by the Ottoman power, and the struggle was henceforth for existence. Abandoned by Venice and unable to obtain succour from any Christian state, Ivan the Black, the son and successor of Stephan, set fire to Zhabliak in 1494, and withdrew with his people to the mountain village of Tzetinye (Cettigne) which has since been abandoned; here he founded the famous monastery and created a bishopric in order to establish the spiritual power at the seat of government. Ivan was one of the greatest heroes of Montenegrin history; according to the national legend, he still sleeps in a cave near his fortress of Obod—to awake when the hour arrives for the expulsion of the Turks from Europe.

The Elective Vladas, or bishops of Cettigne, elected by assemblies of the "people," and consecrated by the patriarch of Ipek. The elective vladas were aided in matters relating to national defence by a civil governor. The institution of a theocratic sovereignty probably saved the country from absorption in the Turkish Empire, the supreme power being vested in a sacrosanct person, whose position was unattainable by ambitious chiefains, and whose holy office precluded the possibility of his defection to Islam. The earlier vladas were left comparatively unmolested by the Turks, and were enabled to devote their attention to the issue of missals and gospels from the printing-press at Obod. But the beginning of the 18th century was marked by renewed Turkish aggression. Cettigne was taken in 1623 and again in 1687, when the monastery of Ivan the Black was blown up by the monks; a tribute was for a time imposed on the mountaineers, but the bolder spirits maintained their resistance in the heights, and the invading armies found it impossible to prolong their stay in these inhospitable regions.

In 1660 it was decided to continue the hereditary principle with the theocratic system, and Danilo Petrovich of Negush, the first ruler of the present reigning family, was nominated vladka with power to select his successor from among his relatives. The succession was henceforth regularly from uncle to nephew, owing to the rule of celibacy imposed on the monastic order. The reign of Danilo I. was memorable for the massacre of the Moslems settled in the principality ("the Montenegrin vipers") on Christmas Eve 1702, the great defeat of the Turkish invaders at Tzaralvat (1712), the capture of Cettigne by the Turks and the throwing down of the third time of its monastery (1714), and the inauguration of the intimate relations which have ever since existed with Russia by the visit of the vladika to Peter the Great in 1735. With Russian aid Danilo was enabled in some degree to repair the ruin which had overtaken his little realm. In the time of his successor Sava (1737-1782) an impostor named Stephan Mali, who represented himself as the Russian emperor Peter III., won the confidence of the Montenegrins, and governed the country with ability for several years (1768-1773), the mountaineers defeating the combined efforts of the Turks and Venetians to remove him. He was eventually assassinated by a Greek suborned by the pasha of Scutari. Peter I. (1782-1830), the greatest of the vladas, took part in the war of Austria and Russia against Turkey (1788-92), but was abandoned by his allies in the treaties of Sistova and Jassy. He nevertheless completely routed the Turks in the battle of Krusa (1796), annexed the Brda region to the principality, and obtained a formal recognition of Montenegrin independence from the sultan in 1799. In concert with the Russians he besieged the French in Ragusa (1806), and in 1813 and 1814 expelled them from the Bocche di Cattaro with the aid of a British fleet under Admiral Fremantle. The much-coveted seaport, however, was almost immediately occupied by an Austrian force. Peter I. reorganized the internal administration and promulgated the first Montenegrin code of laws. After his death he was canonized as a saint by the people. His successor Peter II. (1830-1851), a poet, statesman and reformer, as well as a capable military chief, instituted a senate (1831), abolished the office of civil governor (1832), revived the national printing-press, and did much to educate and civilize his people. He was buried by desire on the summit of Mount Lovchen that his spirit might survey his beloved land. He was the last of the vladas; his nephew Danilo II. (1851-1860) at once declined the ecclesiastical dignity, and the throne of Montenegro passed to his younger brother, who maintained the succession on his direct male descendants. He defeated the Turks near Ostrog in 1853, but refrained from attacking them during the Crimean War. His pacific policy produced much discontent among the warlike mountaineers, which culminated in an open revolt. His demand for the recognition of Montenegrin independence and other claims were set aside by the Congress of Paris. In 1858 his brother Mirko, "the Sword of Montenegro," routed the Turks with great slaughter at Grahovo. In 1855 Danilo II. promulgated a new code, assuring civil and religious liberty to his subjects. On the 11th of August 1860 he was shot at Persano on the Bocche di Cattaro by a Montenegrin whom he had exiled after the revolt, and died two days afterwards. He left no male offspring, and was succeeded by Nicholas, the son of his brother Mirko.

Shortly after the accession of Prince Nicholas (Aug. 13, 1860), an insurrection broke out in Herzegovina, and the sympathy which the mountaineers displayed with their kinsmen led to a rupture with Turkey (1861). The prince, thus deprived of the support of hisSubjects, abdicated the throne and went to Ostrog by the Prince's father Mirko; the war proved disastrous, owing to the superior armament and discipline of the Turkish troops, and severe terms were imposed on the principality by the convention of Scutari (Aug. 31). During the fourteen years of peace which followed, the country suffered greatly from pestilence and famine. Within this period a series of reforms were carried out by the prince: the army was reformed and reorganized, an educational system was initiated, and a constitution under which the prince surrendered various prerogatives to the Senate was granted. In 1869 the Krivoshivs, or Serb inhabitants of the northern shores of the Bocche di Cattaro, rose against the Austrian government; the excitement in Montenegro was intense, but the prince succeeded in checking the warlike ardour of his subjects. The revolt in Bosnia and Herzegovina in 1875 had more important consequences for the principality. On the 2nd of July 1876 Prince Nicholas, in alliance with Prince Milan of Servia, declared war against Turkey and invaded Herzegovina. A victory was gained at Vuchil (July 28), and Medun was captured; but the Servian troops, however, gave up their arms on November 14. In the following spring the determination of Russia to take the field against Turkey encouraged the Montenegrins to renew the war. The Turks succeeded in occupying Ostrog, but were subsequently repulsed; the greater part of their forces was soon withdrawn to Bulgaria, and Prince Nicholas captured successively Niksich, Antivari and Dulcigno. The recovery of the seaboard, which had belonged to Montenegro in the middle ages, was perhaps the principal achievement of the war. The enlargement of territory stipulated for by Russia under the treaty...
of San Stefanó (March 3, 1878) would have brought Montenegro into close contiguity with Servia, thus facilitating the eventual union of the two races and closing the path of the Austrians towards the Aegean. The Berlin Treaty (article xxviii.) gave to Montenegro Nikšić, Spuz, Podgoriča, Plava, Gusiņye and Antiwarı, but restored Dulcigno to Turkey. The resistance of the Moslem inhabitants of Plava and Gusiņye to annexation led to long negotiations, and eventually the “Corti Compromise” was agreed to by a conference of the Powers at Constantinople (April 18, 1880). Plava and Gusiņye were to be restored to Turkey, while the Montenegrin frontier was extended so as to include the Hoti and the greater part of the Klementi tribes. This arrangement, which could hardly have proved successful, was not carried out by Turkey, and the Powers subsequently decided to annex Dulcigno to Montenegro in exchange for Plava and Gusiņye. The Porte interposed delays, though consenting in principle, and the Albanian League (see ALBANIA) assumed a menacing attitude. On the 26th of September the fleets of the Powers under Admiral Seymour appeared off Dulcigno, and the British government shortly afterwards proposed to occupy Smyrna. On the 17th of November the Porte yielded; on the 22nd of December Turkey and Montenegro signed a treaty, and Montenegro obtained possession of Dulcigno. The present frontier, as already described, was shortly afterwards delimited by an international commission.

With the exception of some frontier troubles, the years since 1880 have been spent in peace, and the country has advanced in prosperity under the autocratic but enlightened rule of Prince Nicholas. The relations with Turkey, the traditional foe, have improved, while those with Austria have become less friendly. In July 1893 the four-hundredth anniversary of the foundation of the printing-press at Obod was celebrated at Cetitigé, several foreign universities and learned bodies being represented at the festivities. In September 1896 the bi-centenary of the Petrovich dynasty was commemorated. The marriage in the same year of Princess Helen, fourth daughter of Prince Nicholas, with the crown prince of Italy, subsequently King Victor Emmanuel III., led to an increased influence of Italian influence in the principality. In December 1900 Prince Nicholas assumed the title of “Royal Highness.” In October 1906 the first Montenegrin parliament assembled at Cetitigé; and on the 28th of August 1910, Prince Nicholas (q.v.) assumed the title of king.

MONTE OLIVETO MAGGIORE, a monastery of Tuscany, Italy, 6 m. S. of Ascanio. It was founded in 1230, and is mainly celebrated for the beautiful frescoes in the monastery court, which are by Luca Signorelli (1447–1498) and Antonio Bazzi, called Sodoma (1503), representing scenes from the legend of St Benedict. The church and library contain fine inlaid woodwork by Fra Giovanni da Verona.

MONTPELUCIANO, a town and episcopal see of the province of Siena, Tuscany, Italy, 44 m. S.E. of Siena by rail. Pop. (1901) 6288 (town); 15,384 (commune). The town, 6 m. W. of

MONTE OLIVETO MAGGIORE—MONTEREY

773

the station, crowns the summit of a hill (184 ft.), and is surrounded by medieval walls. It is not traceable in history before A.D. 715. It was under the protection of Siena till 1205, when it declared for Florence and henceforward passed from one mistress to the other, until early in the 16th century when it finally became Florentine. In 1361 it became an episcopal see. Most of the buildings belong to the Renaissance; except the castle, the 14th-century Palazzo Pubblico, and the portals of two or three churches, especially that of S. Maria (13th century). There are a number of fine private houses, some built by Antonio da Sangallo the elder (1455–1534) and Baldassare Peruzzi (1481–1536) and others by Vignola (1507–1573). The beautiful church of the Madonna di S. Biagio—which Sangallo’s masterpiece—was built in 1518–1537. The cathedral built by Bartolommeo Ammannati (1570), modified by Ippolito Scalza, and completed in 1680 (with the exception of the façade, which is still unfinished) contains a large altar-piece by Taddeo di Bartolo di Siena, and the fragments of an imposing monument erected in 1427–1436 by the Florentine architect Michelozzo in honour of Bartolommeo Aragazzi, secretary of Pope Martin V., which was taken down in the 18th century. The stately palace of S. Agostino is probably also Michelozzo’s work. Montepulciano is famed for its wine, and was the birthplace of the scholar and poet Angelo Ambrogini (1454–1494), generally known as Poliziano (Poet) and of Cardinal Bellarmine (1542–1621).

See F. Bargagli-Petrucci, Montepulciano, Chiusi, &c. (Bergamo, 1907).

MONTEREAU, a town of northern France, in the department of Seine-et-Marne at the confluence of the Yonne with the Seine, 21 m. S.E. of Melun by rail. Pop. (1906), 7870. The church dates from the 13th century, with a façade of the Renaissance period. The industries include the manufacture of porcelain, fire-proof and decorative bricks, boots and shoes and agricultural machines and colours, varnish, &c. Among the institutions are a tribunal of commerce and a chamber of arts and manufactures.

Montereau was in the beginning of the 15th century a place of some importance. Here, on the bridge over the Yonne, Jean Sans-Peur, duke of Burgundy was assassinated in the presence of the Dauphin, afterwards Charles VII., in 1419. In 1438 the town was captured by Charles VII., and during the wars of religion it was several times taken and retaken. In 1814 Napoleon gained a victory at Montereau over the Württemberg troops under Schwarzenberg, and in memory of this his statue has been erected on the bridge.

MONTEREY, a city of Monterey county, California, U.S.A., on the Pacific coast, about 90 m. in a straight line S. by E. from San Francisco, at the S.E. extremity of the Gulf of Monterey, a great open bay 22 m. wide from headland to headland and facing S.W. The harbour is protected by a peninsula extending N.W. Pop. (1900), 1748, largely of Spanish descent; (1910) 4923. It is served by the Southern Pacific railroad, and for freight by the Pacific Coast Steamship Co. It is built in an amphitheatre formed by gently sloping pine-clad hills. In 1881 the Southern Pacific Company erected the Del Monte hotel, with beautiful grounds several miles in extent, since then the city has come to be one of the favourite resorts of the Pacific Coast. The difference between the mean temperatures of the coldest and warmest months of the year (rarely below 45° or above 66° F. respectively) is from 10° to 20°; while the thermometer rarely registers below freezing or above 80° F. Within the city limits there is a United States Army post, the Presidio of Monterey, with a musketry school. There are sadine canneries here and good salmon and other fishing; some salmon are shipped to Germany to be smoked. In 1907 the south side of the Gulf of Monterey was made by the state legislature into a preserve for squid and other food for salmon. To San Francisco, Hawaii, Alaska, and elsewhere, Monterey ships annually about 60,000 tons of crude oil, piped here into great steel tanks from the Coalinga oil fields 112 m. away. Sand lime brick is manufactured here.
Before the coming of the Americans, Monterey was the gayest and most ambitious city of California. It was discovered by Sebastian Vizcaino in December 1603, and was named in honour of the then viceroy of New Spain. For a time all trace was lost of Monterey, but in May 1770 the bay was found again by Junipero Serra and Captain Gaspar de Portolá. The San Carlos mission of the Franciscans was founded on the 3rd of June 1770, and a presidio was completed in 1778. Monterey, in Carmel Valley, whether the mission was almost immediately removed, Father Junipero built a church, in which his remains now rest. In 1801 a statue, representing Junipero stepping from a boat, was erected on the site of the old Mexican fort, on a hill near the landing-place of both Vizcaino and Junipero. Monterey necessarily played a prominent part in the jealousies that divided the north and south; the rivalry of Los Angeles for the dignity of capital being a powerful influence in politics from 1827-1846. In 1845 Los Angeles gained the prize, but in 1847 the American authorities again made Monterey the capital. Even in these years the treasury, custom-house and military headquarters had remained at Monterey. In 1848 it was captured and momentarily held by a Buenos Aires privateering expedition under Colonel A. Colton. The United States, with the flag of the United States for a day, and here on the 7th of July 1846, Commodore J. D. Sloat again raised the same flag, which this time was not to come down again. The first American newspaper on the Pacific coast was published at Monterey; and the convention that framed the first constitution of the state met here in September 1849 in Colton Hall, still standing and originally built for a schoolhouse by Walter D. Colton, the first alcalde under American rule. Monterey was never the capital of the new state, and its importance declined after the discovery of gold near Sacramento, San Francisco becoming the leading city. In 1872 the county-seat was removed from Monterey to Salinas. For many years Monterey remained one of the most Spanish towns of California, and though tourists have somewhat disturbed its peace and checked its decay, it still retains much of the quaint aspect and the drowsy contentment of spirit of Mexican days.

MONTERREY (usually spelled Monterey in English), a city of Mexico, is the capital of the state of Nuevo León, 606 m. by the old wagon road, and 671 m. by the Mexican National railway N. by W. of the city of Mexico, in lat. 25° 40' N., long. 100° 25' W. Pop. (1900), 62,666. Railway communications are provided by the Mexican National with the United States, with the national capital and southern Mexico, and with Matamoros, and by the Belgian line with Tampico on the Gulf coast, and with Treviño, or Venadito, on the Mexican International line, which gives access to the iron deposits of Durango. The city stands 1624 ft. above sea-level, between two spurs of one of the Sierra Madre ranges—the Cerro de la Silla (4140 ft.) on the east, and the Cerro de las Mitras (3618 ft.) on the west. The Santa Catarina river furnishes water-power for some of its industries. The surrounding district is fertile, and the rainfall about 22 in. The climate is dry and mild, and the city is frequented in winter by invalids from the United States. Monterey is laid out with broad, straight streets crossing each other at right angles, and spreads over a large area. It is the see of the bishop of Linares, and has a large cathedral and many fine and numerous edifices. Among the public edifices are the government palace, municipal hall, national college, girls' college, medical school, public hospital, theatre and penitentiary. Its public works include an interesting old reservoir, called the "Ojo de Agua," and the "Puente Nuevo" (new bridge). Monterey is the most important centre of northern Mexico, and large sums of foreign capital have been invested in its industries. Among its manufactures are woolen mills, smelting works, brass and iron foundries, a steel producing plant, sawmills, flour-mills, breweries, and a carriage and wagon factory. Monterey was founded in 1560 under the name of Santa Lucía de León; and in 1596, as Monterey, was raised to the dignity of a city. In 1777 it became the see of a bishop, now suffragan to the archbishop of Guadalajara. During the war between Mexico and the United States General Zachary Taylor arrived before the city on the 19th of September 1846, with about 6600 men. Monterey was defended by a Mexican force of about 10,000 under General Pedro de Ampudia. On the 20th Colonel John Garland (1792-1861) assaulted the lower (north-eastern) part of the city; he was driven back, but captured one of the forts. The attacks on the other forts on the east were unsuccessful. On the 21st and 22nd General W. J. Worth carried the forts west of Monterey, and on the 23rd attacked the western part of the city, the troops slowly working their way toward the central plaza. On the same day American troops again advanced from the east, and were again forced back. On the morning of the 24th the terms of a capitulation were agreed upon—the Mexicans were permitted to retire, retaining their small arms and one field battery of six pieces with twenty-one rounds of ammunition, and an armistice of eight weeks was arranged. A disastrous flood, caused by heavy rains and the sudden overflow of the Santa Catarina river on the 28th of August 1909, swept away about one-fourth of the city, drowning 1200-1400 persons, and destroying about $10,000,000 worth of property.

MONTE SAN GIULIANO, a town and episcopal see of Sicily, in the province of Trapani, 2 m. N.E. of Trapani, on the summit of an isolated bare hill, 2465 ft. above the sea. Pop. of commune (1901), 28,939; of town, about 3000. The town occupies the site of the ancient Eryx, a city of the Elymni, a people who claimed to be sprung from a mixed settlement of Trojans and Phocians after the fall of Troy (E. A. Freeman, History of Sicily, i. 195, 542), but regarded as Βασιλίακες by the Greeks. The city was famous for the temple of Venus Erycina, to the foundations of which a wall of 12 courses of masonry in the castle probably belongs. The worship was a relic of the Phoenician cult of Astarte. In 415 B.C. the Athenian envoys were shown the treasure of the temple at Eryx as available for the expenses of the war, which treasure turned out to be only silver-gilt and not of solid gold (Thucydides vi. 46). The town must have become a part of the Carthaginian dominion in 405 B.C. It was seized by Pyrrhus in 278 B.C., and was ceded to Rome at the end of the First Punic War. In Roman times the temple (like that of Diana Tifatana, near Catania), possessed territory of its own, being dependent neither on the state nor on any neighbouring town, and a considerable number of female slaves. The place was the residence of the quaestor in charge of the western half of the island, and Verres, as praetor, seems to have spent a good deal of time here. Considerable portions of the city wall are preserved on the north-west; on the east and south the precipitous cliffs formed a sufficient defence. The remains date from a reconstruction of Roman times, in which the material of two earlier periods has been used: the large blocks belonging to the original fortifications bear Phoenician masons' marks; but the long line of towers at regular intervals is a thoroughly Roman characteristic. The castle, dating from the middle ages, with three lofty towers guarding the entrance, occupies the south-eastern extremity of the town. The cathedral, founded in 1314, has a fine porch and Gothic façade.

MONTE SAN SAVINO, a town of Tuscany, Italy, in the province of Arezzo, from which it is 12 m. S.W. by road, 1053 ft. above sea-level, on the southern slopes of Monte Gargano. Pop. (1901), 4850 (town); 8498 (commune). It was the birthplace of the sculptor and architect Andrea Contucci, generally known as Sansovino (1460-1526), and there are various works in the town by him, a loggia opposite the Palazzo Municipale (itself by Antonio da Sangallo the elder and one of his best works), the monastery courts of S. Agostino and S. Giovanni Battista, and some sculptures.

MONTE SANT' ANGELO, a town of Apulia, Italy, in the province of Foggia, 10 m. N. of Manfredonia by road, 2765 ft. above sea-level, on the southern slopes of Monte Gargano. Pop. (1901), 17,369 (town); 21,997 (commune). It has a castle and a famous

1 This has been demonstrated by O. Richter, Über antike Steinmetzzeichen (Berlin, 1885), pp. 43-51.
sanctuary of S. Michele, founded in 401 over a cave in which the archangel is said to have appeared to S. Laurentius, archbishop of Spiontum; the bronze doors, made in Constantinople, bear the date 1076. The octagonal campanile dates from 1273. The portal of S. Maria Maggiore also dates from the 12th century. The Torre de Rotari is a domed building of the Norman period. To the north lies the highest point of the Monte Gargano (3450 ft.). Strabo speaks of an oracle of Calchas on the top of the mountain, and a healing spring at Podalius at the bottom, 12 m. from the sea. See S. Beltramelli, \l' Il Gargano (Bergamo, 1907).

**Montespan, Françoise-Athenais de Pardaillan, Marquise de** (1641-1707), mistress of Louis XIV., was born at the château de Tonnay-Charente (Charente-Inférieure), daughter of Gabriel de Rochechouart, duc de Mortemart. She was educated at the Convent of Saint Mary at Saintes, and when she was twenty she became maid-of-honour to Queen Maria Theresa. She married in January 1663 L. H. de Pardaillan de Gondrin, marquis de Montespan, who was a year younger than herself. By him she had two children, L. H. Pardaillan de Gondrin, duc d'Antin, born in 1665, and a daughter. Her brilliant and haughty beauty was only one of the Montespan's charms; she was a cultivated and amusing talker who won the admiration of such competent judges as Saint-Simon and Mme de Sévigné. She was also a patron of letters, and besides believing in witchcraft and La Reynie, the chief judge of the court before which the famous poisoning cases were brought, places her first visits to La Voisin (p. 219) in 1665. She received from the sorceress love powders concocted of abominable ingredients for Louis XIV., and in 1666 the "black mass" was said by the priest Étienne Guibourg over her with the usual horrible ceremonial. In 1667 she gained her end, becoming Louis XIV.'s mistress in July. Montespan astounded the court by openly respecting his wife's position. He made a scandal by accusing Mme de Montausier of acting as go-between in order to secure the governorship of the dauphin for her husband. He even wore mourning for his wife. Montespan was arrested, but released after a few days' imprisonment. The first of the seven children whom Mme de Montespan bore to the king was born in March 1669, and was entrusted to Mme Scarron, the future Mme de Maintenon, who acted as companion to Mme de Montespan while the king was away at the wars. Her children were legitimatized in 1673 without mention of the mother's name for fear that Montespan might claim the title. In 1671 Louis XIV. became duc de Maintenon, and his second, Louis César, comte de Vexin and the third, Louise Françoise, demesneil of Nantes (afterwards duchess of Bourbon). Meanwhile Montespan had been compelled to retire to Spain, and in 1674 an official separation was declared by the procureur-général Achille de Harlay, assisted by six judges at the Châtelet. When Louis's affections showed signs of cooling, Mme de Montespan had recourse to magic. In 1675 absolution was refused to the king, with the result that his mistress was driven from the court for a short time. It has been thought that she had conceived the intention of poisoning even as early as 1676, but in 1679 Louis's intrigue with Angélique de Fontanges and her own rejection to the position of superintendent of the queen's household brought matters to a crisis. Mlle de Fontanges died a natural death in 1681, though poisoning was suspected. Meanwhile suspicion was thrown on Mme de Montespan's connexion with La Voisin and her crew by the frequent recurrence of her maid's name, Mlle Desoelliets, in the evidence brought before the Chambre Ardente. From the end of 1680 onwards Louis XI., Colbert and Mme de Maintenon all helped to hush up the affair and to prevent further scandal about the mother of the king's legitimated children. Louis XIV. continued to spend some time daily in her apartments, and apparently her brilliance and charm in conversation mitigated to some extent her position of discarded mistress. In 1691 she retired to the Convent of St Joseph with a pension of half a million francs. Her father was governor of Paris, her brother, the duc de Vivonne, a marshal of France, and one of her sisters, Gabrielle, whose vows were but four years old, became abbess of the wealthy community of Fontevraud. Besides the expenses of her house and equipage Mme de Montespan spent vast sums on hostas and charities. She was also a generous patron of letters, and befriended Cornelle, Racine and La Fontaine. The last years of her life were given up to penance. When she died at Bourbon l'Archambault on the 27th of May 1707 the king forbade her children to wear mourning for her. Real regret was felt for her by the duchess of Bourbon and by her younger children—Françoise Marie, Mlle de Blois (1677-1749), married in 1692 to the future regent Orleans, then duc de Chartres, and Louis Alexandre, comte de Toulouse (1678-1737). See P. Clément, Madame de Montespan et Louis XIV. (Paris, 1869); monographs by Arène Housseaye (1865) and by H. Williams (1903); also J. Jair, Louis de la Vallière (Eng. trans., 1898); F. Funck-Brentano, Le Drame des poisons (1899); A. Durand, "Un épisode du grand règne" in Rev. des questions hist. (Paris, 1868); the contemporary memoirs of Mme de Sévigné, of Saint-Simon, of Du Châtelet. Also the proceedings of the Chambre Ardente preserved in the Archives de la Bastille (Arsenal Library) and the notes of La Reynie preserved in the Bibliothèque Nationale. She figured in V. Sardou's play, L'Affaire des poisons (1907).

**Montesquiou, Charles Louis de Secondat, Baron de la Brède et de** (1689-1755), French philosophical historian, was born at the château de La Brède, about 10 m. south-east of Bordeaux, in January 1689, and was baptized on the 23rd of January, 1689. His mother was the wealthy and famous Mme de S. de Péné, the heiress of a Gascon-English family. She had brought La Brède as a dowry to his father, Jacques de Secondat, a member of a good if not extremely ancient house, which seems first to have risen to importance in the early days of the 16th century. The title of Montesquiou came from his uncle, Jean Baptiste de Secondat, "président à mortier" in the parliament of Bordeaux—an important office, which, as well as his title, he left to his nephew. Montesquiou was in his youth known as M. de la Brède. His mother died when he was seven years old, and when he was eleven he was sent to the Oratorian school of Jullié, near Meaux, where he stayed exactly five years, and where, as well as afterwards at Bordeaux, he was thoroughly educated. The family had long been connected with the law, and Montesquiou was destined for that profession. His father died in 1713, and a year later Montesquiou was admitted counsellor of the parliament. In little more than another twelvemonth he married Jeanne Lartigue, an heiress and the daughter of a knight of the order of St Louis, but plain, somewhat ill-educated, and a Protestant. Montesquiou's wife had not married as a maid of honour, but as a woman of affec- tion or fidelity towards his wife, but there is every reason to believe that they lived on perfectly good terms. In 1716 his uncle died, leaving him his name, his important judicial office and his whole fortune.

He continued to hold his presidency for twelve years, and took part in the proceedings of the Bordeaux Academy, to which he contributed papers on philosophy, politics and natural science. He also wrote much less serious things, and it was during the earlier years of his presidency that he finished, if he did not begin, the Lettres persanes. They were completed before 1713, and appeared in that year anonymously, with Cologne on the title-page, but they were really printed and published at Amsterdam. In the guise of letters written by and to two Persians of distinction travelling in Europe, Montesquiou not only satirized unmercifully the social, political, ecclesiastical and literary follies of his day in France, but indulged in a great deal of the free writing which was charac- teristic of the tale-tellers of the time, and which, like the moralized grandpaper, was naturally attracted the majority; and the Lettres persanes were very popular, passing, it is said, through four editions within the year, besides piracies. Then the vogue suddenly ceased, or at least editions ceased for nearly nine years to appear. It is said that a formal ministerial prohibition was the cause of this, and it is not improbable; for, though the regent and Guillaume Dubois must have enjoyed the book thoroughly, they were both shrewd enough to perceive that underneath its playful exterior there lay a spirit of
very inconvenient criticism of abuses in church and state. The fact is that the Lettres persanes is the first book of what is called the Philosophe movement. It is amusing to find Voltaire describing the Lettres as a "trumpet book," as "beau which anybody might have written easily." It is not certain that, in its peculiar mixture of light badinage with not merely serious purpose but gentlemanlike moderation, Voltaire could have written it himself, and it is certain that no one else at that time could.

The reputation acquired by this book brought Montesquieu much into the literary society of the capital, and he composed for, or at any rate contributed to, one of the coterie of the day, the clever but rather rhetorical Dialogue de Sylla et d'Eucrate, in which the dictator gives an apology for his conduct. For Mlle de Clermont, a lady of royal blood, a great beauty and a favourite queen of society, he wrote the curious prose-poem of the Temple de Goûde. This is half a narrative, half an allegory, in the semi-classical or rather pseudo-classical taste of the time, decidedly frivolous and dubiously moral, but of no small elegance in its peculiar style. A lates jeu d'esprit of the same kind, which is almost but not quite certainly Montesquieu's, is the Voyage à Paphos, in which his warmest admirers have found little to praise. In 1725 Montesquieu's last book, his Lettres de Brede et de Paphos, appeared. The chief obstacle requiring residence in Paris was appealed to, and the election was annulled. It is doubtful whether a bantering after Parisian society, or an ambition to belong to the Academy, or a desire to devote himself to literary pursuits of greater importance, or simple weariness of not wholly congenial work determined him to give up his Bordeaux office. In 1726 he sold the life-tenure of his office, reserving the reversion for his son, and went to live in the capital, returning, however, for half of each year to La Brède. There was now no further formal obstacle to his reception in the Académie Française, but a new one arose. Ill-wishers had brought the Lettres persanes specially under the minister André Hercule de Fleury's attention, and Fleury, a precision in many ways, was shocked by them. There are various accounts of the way in which the difficulty was got over, but all seem to agree that Montesquieu made concessions which were more effectual than dignified. He was elected and received in January 1728.

Almost immediately afterwards he started on a tour through Europe to observe men, things and constitutions. He travelled through Italy and Hungary, and even to Russia, as he had proposed. Then he made for Italy, where he met Chesterfield. At Venice, and elsewhere in Italy, he remained nearly a year, and then journeyed by way of Piedmont and the Rhône to England. He stayed for some eighteen months, and acquired an admiration for English character and polity which never afterwards deserted him. He returned, not to Paris, but to La Brède, and to outward appearance might have seemed to be settling down as a squire. He altered his park in the English fashion, made sedulous inquiries into his own genealogy, arranged an entail, asserted, though not harshly, his seigniorial rights, kept poachers in awe and so forth. But these matters by no means engrossed his thoughts. In his great study at La Brède (a hall rather than a study, some 60 ft. long by 40 wide) he was constantly dictating, making abstracts, revising essays, and in other ways preparing his main book. He may have thought it wise to soften the transition from the Lettres persanes to the Esprit des lois, by interposing a publication graver than the former and less elaborate than the latter. The Considerations sur les causes de la grandeur et de la décadence des Romains appeared anonymously without the author's name. This, however, was perfectly well known; indeed, Montesquieu formally presented a copy to the French Academy. But the author's reputation as a jester stuck to him, and the salons affected to consider the Lettres persanes and the new book respectively as the "grandeur" and the "décadence de" M. de Montesquieu; but more serious readers at once perceived its extraordinary merit, and it was eagerly read abroad. A copy of it exists or existed which had the singular misfortune to be annotated by Frederick the Great, and to be abstracted from the Potsdam library by Napoleon. It is said, moreover, by competent authorities to have been the most enduringly popular and the most widely read of all its author's works in his own country; and it was certainly the most frequently and carefully edited. Merely scholastic criticism may of course object to it, as to every other book of the time, the absence of the exactness of modern critical inquiry into the facts of history; but the virtue of Montesquieu's book is in its views, not in its facts. It is (putting Bossuet and Giovanni Vico aside) almost the first important essay in the philosophy of history. The point of view is entirely different from that of Bossuet, and it seems entirely improbable that Montesquieu knew anything of Vico. In the Grandeur et décadence the characteristics of the Esprit des lois appear with the necessary subdivision to a narrower subject. Two things are especially noticeable in it: a peculiarity of style, and a peculiarity of thought. The style has a superficial defect. The page is broken up into short paragraphs of but a few lines each, which look very ugly, which irritate the reader by breaking the sense, and which prepare him to expect an undue and ostentatious sententiousness. On the other hand, the merits of the expression are very great. It is grave and destitute of ornament, but extraordinarily luminous and suggestive. The half-dozen epigrams with the half-dozen eulogies which formed the preface to the book had not a certain connotation of flyingly about it. It is a very short book; for, printed in large type with tolerably abundant notes, it fills but two hundred pages in the standard edition of Montesquieu's works. But no work of the century, except Turgot's second Sorbonne Discourse, contains, in proportion to its size, more weighty and original thought on historical subjects, while Montesquieu has over Turgot the immense advantage of style.

Although, however, this ballon d'essai, in the style of his great work, may be said to have been successful, and though much of that work was, as we have seen, in all probability already composed, Montesquieu was in no hurry to publish it. He went on "cultivating the garden" diligently both as a student and as an improving landowner. He wrote the sketch of Lysimaque for Stanislaus Leszinski; he published new and final editions of the Temple de Goûde, of the Lettres persanes, of Sylla and Eucrate (which indeed had never been published, properly speaking). After allowing the Grandeur et décadence to be reprinted without alterations some half-dozen times, he revised and improved it, and, as a result of his son Charles and his daughter Denise, of whom he was extremely fond. He frequently visited Paris, where his favourite resorts were the salons of Mme de Tencin and Mme d'Aigillon. Yet it seems that he did not begin the final task of composition till 1743. Two years of uninterrupted work at La Brède finished the greater part of it, and two more the rest. It was finally published at Geneva in the autumn of 1748, in two volumes quarto. The publication was, however, preceded by one of those odd incidents which in literature illustrate Clive's well-known saying about courts-martial in war. Montesquieu summoned a committee of friends, according to a very common practice, to hear and give an opinion on his work. It was an imposing and certainly not an unfriendly one, consisting of Charles Jean François Hénault, Helvétius, the financier Etienne de Silhouette, the dramatist Joseph Saurin, Crétillon the younger, and, lastly, Fontenelle—in fact, all sorts and conditions of literary men. They unanimously advised the author not to publish a book which has been described as "one of the most important books ever written," and which may be almost certainly ranked as the greatest book of the 18th century.

Montesquieu, of course, did not take his friends' advice. In such cases no man ever does, and in this case it was certainly fortunate. The Esprit des lois represents the reflections of a singularly clear, original, and comprehensive mind, corrected by forty years' study of men and books, arranged in accordance with a long deliberated plan, and couched in language of remarkable freshness and idiosyncrasy. In the original editions the full title runs L'Esprit des lois: ou du rapport que les lois
doivent avoir avec la constitution de chaque gouvernement, les
mœurs, le climat, la religion, le commerce, &c. It consists of
three large books, which in some editions are grouped in six
parts. Speaking summarily, the first part, containing eight
books, deals with law in general and with forms of government;
the second, containing five, with military arrangements, with
taxation, &c.; the third, containing six, with manners and
customs, and their dependence on climatic conditions; the
fourth, containing four, with economic matters; and the fifth,
containing three, with religion. The last five books, forming
a kind of supplement, deal specially with Roman, French, and
feudal law. The most noteworthy peculiarity of the book to
a cursory reader lies in the section dealing with effects of climate,
and this indeed was almost the only characteristic which the
vulgus took in, probably because it was easily susceptible of
parody and reductio ad absurdum. The singular spirit of
moderation which distinguishes its views on politics and
religion was indeed rather against it than in its favour in
France, and Helvétius, who was as outspoken as he was
good-natured, had definitely assigned this as the reason of his
unfavorable judgment. On the other hand, if not destructive
it was sufficiently critical, and it thus raised enemies on more
than one side. It was long suspected, but is now positively
known, that the book (not altogether with the goodwill of the
pope) was put on the Index, and the Sorbonne projected, though
it did not carry out, a regular censure. To all these objectors
the author replied in a masterly défense; and there seems to be
no foundation for the late and scandalous stories which represent
him as having used Mme de Pompadour's influence to suppress
criticism. The fact was that, after the first snarlings of envy
and incompetence had died away, he had little occasion to
complain. Even Voltaire, who was his decided enemy, was
forced at length to speak in public, if not in private, comple-
mentarily of the Esprit, and from all parts of Europe the
news of success arrived.

Montesquieu enjoyed his triumph rather at La Bède than at
Paris. He was becoming an old man, and, unlike Fontenelle,
he does not seem to have preserved in old age the passion for
society which had marked his youth. He certainly spent much
of his later years in the country, though he sometimes visited
Paris, and on one visit procured the release of his admirer
Laurent Angliviel de La Baumeille from an imprisonment
which La Baumeille had suffered at the instance of Voltaire.
He is said also to have been instrumental in obtaining a pension
for Alexis Piron. Nor did he by any means neglect literary
composition. The curious little romance of Arsace et Isménie,
a short and unfinished treatise on Taste, many of his published
Pensées, and much unpublished matter date from the period
subsequent to the Esprit des lois. He did not, however, five
many years after the appearance of his great work. At the
end of 1754 he visited Paris, with the intention of getting rid
of the lease of his house there and finally retiring to La Bède.
He was shortly after taken ill with an attack of fever, which
seemed to affect his lungs, and in less than a fortnight
he died, on the 10th of February 1755, in the sixty-sixth year of
his age. He was buried in the church of St Sulpice with little pomp,
and the Revolution obliterated all trace of his remains.

The literary and philosophical merits of Montesquieu and his
position, actual and historical, in the literature of France and of
Europe, are of unusual interest. At the beginning of the
next century the vicomte de Bonald classed him with Racine and
Bossuet, as the object of a "religious veneration" among
Frenchmen. But Bonald was not quite a suitable spokesman
for France, and it may be doubted whether the author of
the Esprit des lois has ever really occupied any such position in his
own country. For a generation after his death he remained
indeed the idol and the great authority of the moderate reforming
party in France. Montesquieu is not often quoted, or quoted,
at the present day, and the exact criticism of our time challenges
the accuracy of his facts. Although he was really the founder,
or at least one of the founders, of the sciences of comparative
politics and of the philosophy of history, his descendants and
followers in these sciences think they have outgrown him. In
France his popularity has always been dubious and contested.
It is a singular thing that for more than a century there was
no properly edited edition of his works, and nothing even
approaching a complete biography of him, the place of the
latter being occupied by the meagre and rhetorical Éloges of
the last century. According to his chief admirers, he is hardly
read at all in France to-day, and they attempt to explain
the fact by confessing that Montesquieu, great as he is, is not
altogether great according to French principles. It is not only
that he is an Anglo-maniac, but that he is rather English than
French in style and thought. He is almost entirely dispassionate
in politics, but he lacks the unswerving deductive consistency
which Frenchmen love in that science. His wit, it is said, is
quaint and a little provincial, his style irregular and in no
definite genre.

Some of these things may be allowed to exist and to be
defects in Montesquieu, but they are balanced by merits which
render them almost insignificant. It is on his three principal
works that his fame does and must rest. Each one of these
is a masterpiece in its kind. It is doubtful whether the Lettres
persones yield at their best either in wit or in giving lively pictures
of the time to the best of Voltaire's similar work, though they
are more unequal. There is, moreover, the great difference
between Montesquieu and Voltaire that the former is a rational
reformer, and not a mere persifleur ou frondeur, to whom fault-
finding is more convenient than acquiescence for showing off
his wit. Of course this last description does not fully or always
describe Voltaire, but it often does. It is seldom or never
applicable to Montesquieu. Only one of Voltaire's own charges
against the book and its author must be fully admitted. He is
said to have replied to a friend who urged him to give up his
habit of sneering at Montesquieu, "II est capable de lèse-poésie," and
this is true. Not only are Montesquieu's remarks on poetry
childish (he himself occasionally wrote verses, and very bad
ones), but he is never happy in purely literary appreciation.
The Considerations are noteworthy, not only for the complete
change of style (which from the light and mocking tone of the
Lettres becomes grave, weighty and sustained, with abundance
of striking expression), but for the profundity and originality of
the views, and for the completeness with which the author carries
out his plan. These words—except, perhaps the last clause—
apply with increasing force to the Esprit des lois. The book
has been accused of desultoriness, but this arises, in part at
least, from a misapprehension of the author's design. At
the same time, it is impossible to deny that the equivocal
meaning of the word "law," which has misled so many reasoners,
have sometimes misled Montesquieu himself. For the most part,
however, he keeps the promise of his sub-title (given above)
with fidelity, and applies it with exhaustive care. It is only
in the last few books, which have been said to be a kind of
appendix, that something of irrelevancy suggests itself.
The most important of the Esprit des lois, however, is not that
of a formal treatise on law, or even on politics. It is that of an
incomplete, or original, series of essays on legal and political subjects, put in language of singular suggestiveness and vigour, illustrated by examples which are always apt and luminous, permeated by the spirit of temperate
and tolerant desire for human improvement and happiness,
and almost unique in its entire freedom at once from doctrin-
airism, from visionary enthusiasm, from egotism, and from an
indulgent spirit of system. As for the style, no one who does
not mistake the definition of that much used and much misused
word can deny it to Montesquieu. He has in the Esprit little
ornament, but his composition is wholly admirable. Yet
another great peculiarity of this book, as well as of the Considéra-
tions, has to be noticed. The genius of the author for general-
ization is so great, his instinct in political science so sure, that
the falsity of his premises frequently fails to vitiate his
conclusions. He has known wrong, but he has thought right.

The best edition of Montesquieu is that of Edouard Laboulaye
(7 vols., Paris, 1875-1879), the best biography of Louis Vian

MONTESQUIOU-FÉZENSAC—MONTEVIDEO

(Paris, and ed., 1879). The bibliography of Montesquieu was dealt with by L. Dangeau in 1874. There is known to exist at La Brède a great mass of MS. materials for the Écrits des lois, additional Lettres persanes, essays, and fragments of all kinds, diaries, letters, notebooks and so forth. The present possessors, however, who represent Montesquieu, long refused permission to examine these to all editors and critics, and they were chiefly known by a paper contributed in 1834 to the Transactions of the Academy of Agen. At last in 1851 Baron Charles de Montesquiou published Découvertes et réflexions, and in 1859 Baron Gaston de Montesquiou added Pensées, &c. Nothing, however, of much interest has yet appeared. For a thorough student L'Ésprit de Montesquieu by A. Chaux (1858) has value, for it is written, with some ability; from the point of view not very uncommon, that of a convinced Roman Catholic, anti-parliamentarian and anglophone critic, who regards Montesquieu as an "evangelist of social atheism" and the like. The view is quite untenable but useful as a corrective; An cycle in Quarterly Review, No. 394, April 1903 (G. SA.) may be also consulted.

MONTESQUIOU-FÉZENSAC, ANNE PIERRE, MARQUIS DE (1730-1798), French general and writer, was born in Paris on the 17th of October 1730, of an ancient family of Armagnac. He was brought up with the children of the king of France, and showed some taste for letters. He entered the army in 1754, was successively colonel of the Grenadiers and the Royal-Vauxs regiment, and in 1760 was made maréchal-de-comp. Some pieces of verse and several comedies, signed by "M. de Montesson," were produced. He was elected deputy to the states general of 1789 by the nobles of Paris, and, animated by Liberal ideas, he soon joined the Third Estate, and seconded Necker's financial schemes. He served on the committee charged with the issue of assignats, and was named president of the Constituent Assembly on the 14th of March 1791. In May 1791 he was promoted lieutenant-general, served under Lafayette, and in February 1792 was given the command of the Army of the South. In September of the same year he completed the conquest of Savoy, but in November 1792 he was accused of royalist leanings, and had to take refuge in Switzerland. In 1795 his name was erased from the list of émigrés and he returned to Paris, where he died on the 30th of December 1798.

See F. L. Roederer, Éloge de Montesquieu, reprinted in Roederer's Works (1855-1859).

MONTESPONS, CHARLOTTE JEANNE BÉAUDA DE LA HAYE DE RIOU, MARQUISE DE (1757-1805), was born in Paris of an old Breton family. About 1754 she married Jean Baptiste, marquis de Montespans. His wife, Charlotte, was of such intelligence attracted the attention of Louis Philippe, duke of Orleans, whom she secretly married in 1773 with the authorization of the king. For her husband's amusements she set up a little theatre and wrote several plays, in the acting of which she herself took part. She was imprisoned for some time during the Terror, but was released after the fall of Robespierre, became the friend of the empress Josephine, and was a prominent figure at the beginning of the empire.

The best edition of her works appeared under the title of Oeuvres anonymes in 1782-1785. See Charles Collot, Journal (1868); the Mémoirs de St Simon, Madame de Genlis, the duchesse d'Abbrantès and Mme de Laval; G. Stenger, La Société de la marquise de Montespans, in the Nouvelle revue (1902); J. Turquin, Madame de Montespans douteraine d'Orléans (Paris, 1904); and G. Capon and R. Ivo-Plesis, Les Théâtres clandestins du xviie siècle (1904).

MONTEVERDE, CLAUDIO (1567-1643), Italian priest and musician, was born at Cremona in May 1567; he was engaged at an early age as violinist to the duke of Mantua, and studied composition under Ingegneri, the duke's maestro di capella. His bold experiments, while bringing upon him the attacks of Artusi and Banchieri (q.v.), led to discoveries which exercised a lasting influence upon the progress of musical art. He was the first to make deliberate use of unprepared dissonances, or as they are now known as functional harmony, thus discarding the rules and constituting a revolution against the laws of 16th century music. He employed them first in his madrigals, where they are a sign of decadence, but afterwards introduced them into music of another kind with such excellent effect that their value was universally recognized. Before 1595 Monteverde was married to the singer Claudia Cattaneo, who died in 1607. In 1602 he succeeded Ingegneri as maestro di capella; and in 1607 he produced, for the marriage of Francesco Gonzaga, his first opera, Ariana, in which he employed the newly-discovered discords with irresistible effect. Though he did not invent the lyric drama—Peri's Euridice having been produced at Florence in 1600—he raised it to a level which distanced all contemporary composition. His second opera, Orfeo, composed in 1608, was even more successful than Ariana. In 1613 Monteverde was invited to Venice, as maestro di capella at St Mark's, with a stipend of 300 ducats, which in 1616 was raised to 400. Here he composed much sacred music, the greater part of which is lost. In 1630 he wrote another grand opera, Proserpina rapita. He did not become a priest until 1632. In 1639 he produced L'Adone, and in 1641 Le Nosoce di Enea and Il Ritorno d'Ulisse. He died in Venice on the 29th of November 1643. Monteverde's harmonic innovations and power of musical rhetoric seemed to put an end to the school of Palestrina, and led the way to modern music. (See Music.)

MONTEVIDEO, SAN FELIPE Y SANTIAGO DE, capital and chief port of Uruguay, and capital of the department of Montevideo, on the northern shore of the Rio de la Plata estuary, 120 m. E.S.E. of Buenos Ayres, in lat. 34° 54' 33" S., long. 59° 12' 18" W. Pop. (1908, estimate), 312,046. The old city (ciudad vieja) occupies a low rocky headland that projects westward from the estuary and an almost circular bay which forms the harbour; it was once enclosed with walls and defended by small forts, all of which have been removed. The new city (ciudad nueva and ciudad novisima) lies westward on a beautiful tract of rolling country and is extending northward and westward toward the eastern shore of the bay. The site of the old city resembles a whale's back in shape; it slopes gently to its western extremity at Punta Sarandi and to the water's edge on either side. The general plan is that of rectangular squares, except at the western extremity of the old city and its union with the newer or extra-mural city, on the line of the old ramparts, known as Calle de la Ciudadela. The streets are well paved and have sufficient slope at all points to give easy surface drainage; Montevideo has the reputation of being one of the cleanest cities of the world. The rainfall is ample (about 44 in. a year), and the prevailing winds help to clean the streets. The westerly winds, however, sometimes bring across the bay the offensive smells of the great abattoirs and meat-curing establishments (saladeros) at the foot of the Cerro. The mean annual temperature is about 62° F. An abundant water supply is brought from the Santa Lucia River, 32 m. distant, with a receiving reservoir at Piedras, 100 ft. above the level of the Plaza de la Independencia. The ciudad vieja is largely devoted to commercial, shipping and financial interests. The government edifices, large retail shops and most of the fine urban residences are in the ciudad nueva, while most of the urban industries, the railway stations and the dwellings of the poorer classes are in the ciudad novisima. Beyond these is a fringe of suburbs (La Union and Paso Molino), and on the western side of the bay is the sprawling suburb of Cerro, largely industrial in character. In 1908 eight tramway lines (all electric but one) extended out to these suburbs, some of the lines extending to the bathing resorts of Ramirez and Pocitos and the Buque cemeteries on the eastern coast.

The principal street, which is considered one of the finest boulevards in South America, is the Calle 18 de Julio, extending eastward from the Plaza de la Independencia to the suburb of Cordón; one of its features is its Sunday morning market, occupying the whole street from the Plaza de la Independencia to the Plaza Libertad, a distance of half a mile—a survival of the old market that existed here at the fortified entrance to the city in the 16th century. In the centre of the city, 10 years of its history. There are seven plazas, or squares, within the urban limits: Zahala or Rincon, Constitución or Matriz, Independencia, Libertad or Cagancha, Treinte y Tres, Flores and Frutos; and two suburban parks or public gardens: the Paseo del Prado and Parque
MONTE VULTURE

Urbano. The Plaza de la Independencia stands at the junction of the old and new towns and is the centre of the city's political and social life. This square is distinguished for a uniform and nearly complete line of colonnades in front of the buildings surrounding it. The Paseo del Prado, which ranks high among the public gardens of South America, is beautifully situated beyond the suburb of Paso Molino, 3 m. from the city. The Paseo was originally the quinta of a German of cultivated tastes named Joseph-Buschenthal, who spent a fortune in its adornment. The Parque Urbano, at the Playa Ramirez bathing resort, is a modern creation. The buildings of Montevideo are chiefly of brick and broken stone, covered outside with plaster and stucco, of one to three stories, with flat roofs, usually surmounted by a square tower, or mirador. The roofs, or azoteas, are largely used for domestic purposes, or roof gardens. The city contains a large number of handsome edifices, both public and private, among which are the Bolsa, Government House, municipal hall, cathedral, Cabildo, Hospital de Caridad, insane asylum, Italian hospital, Teatro Solis, Ateaneum, and the Club Uruguayo. The Bolsa (exchange), custom-house, cathedral, and Cabildo are the four buildings that is a copy of the Bolsa exchange. The cathedral faces on the Plaza de la Constitución. Its two square towers rise 133 ft. above the pavement, and these, with the large dome behind, rise far above the surrounding buildings and make a very conspicuous landmark. The church was consecrated in 1804, and in 1869 was raised to the dignity of a cathedral. Montevideo is now the seat of a small archiepiscopal see with only two suffragan dioceses. Directly across the plaza is the old Cabildo, a plain, heavy-looking two-storied edifice of the colonial period, the seat of municipal administration during Spanish rule, but now occupied by the two chambers of the Uruguayan Congress and by the higher police authorities of the city.

The people of Montevideo maintain more than forty charitable associations, including the Caridad (charity) hospital on Calle 23 de Mayo, and the insane asylum in the suburb of La Union, both built and largely supported from the proceeds of frequent lottery drawings. They also maintain a beggars' asylum and a foundlings' asylum. The national museum (founded in 1825) and public library (founded 1833) are in one wing of the Solis theatre. There is a British hospital (founded 1857, the present edifice dating from 1867) chiefly for the use of sailors, an Anglican church in Calle Santa Teresa dating from 1847, and a handsome Italian hospital of modern construction. The University, in Calle Uruguay, has faculties of law, medicine, letters, mathematics, engineering, and some minor groups of studies, including agriculture and veterinary science. The government maintains two normal schools, a school of arts and trades (artes y oficios), and a military school.

The harbour of Montevideo consists of a shallow bay, circular in shape and about 24 m. from shore to shore, and an outer roadstead exposed to the violent winds of this latitude, where the larger ocean-going steamers were compelled to anchor before the construction of the new port works. In 1899 the Uruguayan government entered into a contract for the dredging of the bay, the construction of two long breakwaters, the dredging of a channel to the harbour, and of a great basin and docks in front of the city. Surtaxes were imposed on imports and exports to meet the expenditure, and work was begun in 1901. In 1908 the breakwaters and the greater part of the dredging had been completed, and the entrance channel, with a minimum depth of 24½ ft., permitted the admission of large steamers. Another important improvement, for which a concession was given to an English syndicate and work was begun in 1909, is the construction of an embankment and new shore line on the south side of the city, to be finished in five years at a cost of $7,271,116. There are three large dry docks connected with the port, known as the Mauá (275 ft. long, inside) and the Gouinouh (500 ft.) on the east side of the bay, and Jackson & Cibils (450 ft.) on the west side at the foot of the Cerro. Four railways terminate at Montevideo, one of them (the Central Uruguay) extending to the Brazilian frontier. In 1908 20 lines of ocean-going steamers made regular calls at the port and several lines of river steamers ran to Buenos Aires and the ports of the Paraná, Paraguay and Uruguay rivers. The exports consist chiefly of livestock, jerked beef, hides, wool, and other animal products, wheat, flour, corn, linseed, barley, hay, tobacco, seal skins, fruit, vegetables, and some minor products. Manufactures exist only to a limited extent and chiefly for domestic consumption.

The suburbs of Montevideo include the fashionable bathing resorts of Playa Ramirez and Pocitos on the coast east of the city, the inland suburbs of Paso Molino and La Union, and the industrial town of Cerro, across the bay. The Flores Island quarantine station is 12 m. east of the city. The station was formerly on Rat Island (within the bay), which is now used as a public deposit for inflammables. The chief point of interest in this suburb is the conical hill known as the Cerro, or "mount," from which the city takes its name, on which stands an old Spanish fort, sometimes garrisoned and sometimes used for the incarceration of political prisoners. Its elevation is 486 ft. (Reclus), and a lighthouse rises from within the fort carrying a red light that can be seen 25 m. distant. Montevideo was founded in 1726 through the efforts of Don Mauricio Zabala, governor of Buenos Aires, who wished to check the advance of the Portuguese on this side of the La Plata. A small military port had existed there since 1717, but efforts to create a town had been fruitless until Zabala offered to make hidalgos of the first settlers and to give them cattle and sheep. The first families to accept this offer came from the Canary Islands in 1726 under the direction of Don Francisco Alzeibar; they were followed by others from Andalusia and some of the Spanish-American settlements. Its growth at first was slow, but on the abolition of the Cadiz monopoly in 1778 it became a free port and its trade increased so rapidly that it soon became one of the chief commercial centres of South America. The city was captured in 1807 by a British expedition under Sir Samuel Auchmuty, but was abandoned when the expedition against Buenos Aires under General Whitelocke was defeated. In 1808 the governor of Montevideo established an independent state, but the Buenos Aires declaration of independence in 1810 the Spanish forces were concentrated in Montevideo and held it until expelled in 1814 by the Argentine land and sea forces under General Alvear and Admiral Brown. The dissensions following the expulsion of the Spanish and the rivalries of Argentina and Brazil over the possession of Uruguay, then commonly termed the "Banda Oriental," greatly reduced the population of the city and partially destroyed its trade. It was made the capital of the republic in 1828 and had partially recovered its population and trade when the disastrous struggle with Rosas, dictator of Buenos Aires, broke out and the city was subjected to a nine years' siege (1843-52), the investment being conducted by General Orbé, and the defence by General Paz. In 1864-65 Brazil intervened in the affairs of the republic, blockaded the port, and reinstated ex-president Flores. The war with Paraguay that followed, which lasted until 1870, made Montevideo the base of supplies for the Brazilian army and navy and added largely to its trade and wealth. The valuation of the city and suburbs, which was $14,356,000 in 1860, was $74,000,000 in 1872. In addition to the reckless speculation of this period, there were continued political dissensions, repeated dictatorships and financial mismanagement on the part of the government. Not the least of these burdens were the personal and irregular drafts of some of the executives upon the treasury and revenue officers, particularly the custom-house of this port, upon which the republic depended for the major part of its revenue. The commercial and financial collapse that followed lasted through the greater part of the last three decades of the century; but settled government and improved finances subsequently contributed to a slow but steady recovery in the trade and industrial activities of the city.

MONTE VULTURE (anc. Vultur), a mountain of Basilicata, Italy, in the province of Potenza, the summit of which is about
MONTFAUCON—MONTFLEURY

5 m. S. of Melfi. It is an extinct volcano rising to 4365 ft. above sea-level, belonging in Roman times to Apulia, and lying on the boundary between it and Lucania. The crater is densely overgrown with oaks and beeches which harbour wild boars and wolves. There are two small lakes. On the banks of the upper lake stand the Capuchin monastery of San Michele and the picturesque ruined church of Sant’ Ippolito. The city of Rionero in Volturé is pleasantly situated 37 m. by rail N. of Potenza, at the foot of Monte Vulture. Pop. (1901), 17,834. It does not seem to be older than the first half of the 17th century. In 1851 it suffered severely from an earthquake.

See G. de Lorenzo, Venosa et la regione del Vulture (Bergamo, 1906).

MONTFAUCON, BERNARD DE (1655-1741), French scholar and critic, was born at the château of Soulage (now Soulatgé, in the department of Aube, France), on the 13th of January 1655. Belonging to a noble and ancient line, and destined for the army, he passed most of his time in the library of the family castle of Roquetaillede, devouing books in different languages and on almost every variety of subject. In 1672 he entered the army, and in the two following years served in Germany under Turenne. But ill-health and the death of his parents brought him back to his studious life, and in 1675 he entered the cloister of the Congregation of St Maur at La Daurade, Toulouse, taking the vows there on the 13th of May 1676. He lived successively at various abbeys—at Sorèze, where he specially studied Greek and examined the numerous MSS. of the convent library, at La Grasse, and at Bordeaux; and in 1687 he was called to Paris, to collaborate in an edition of Athanasius and Chrysostom, contemplated by the Congregation. From 1698 to 1701 he lived in Italy, chiefly in Rome in order to consult certain manuscripts, those available in Paris being insufficient for the edition of Chrysostom. After a stay of three years he returned to Paris, and retired to the abbey of St-Germain-des-Prés, devoting himself to the study of Greek and Latin MSS. and to the great works by which he established his reputation. He died suddenly on the 21st of December 1741. His first publication, in which he was assisted by Jacques Loppin and Antoine Pouget, was the first volume of a never completed series of previously unpublished Analecta graeca (1688). In 1690 appeared La Vertu de l'histoire de Júdith, Athanasii opera omnia, still the best edition of that Father, which was issued with a biography and critical notes in 1698. In connexion with this may be mentioned Collectio nova patrum et scriptorum graecorum (1706), containing some newly discovered works of Athanasius, Eusebius of Caesarea, and the Topographia christiana of Cosmas Indicopleustes. His copious Diarium italicum (1702) gives an account of the principal libraries of Italy and their contents; this work has been translated into English by J. Henley (1725). The Palaeographia graeca (1708), illustrating the whole history of Greek writing and the variations of the characters, has not yet been superseded; in its own field it is as original as the De re diplomatica of Malbion. In 1713 Montfaucon edited Hexaplorum originis sive supremi, not superseded till the work of Field (1895); and between 1718 and 1728 he completed his edition of Joannis Chrysostomi opera omnia. His L’Antiquité expliquée à l’intenté de représenter en figures (1716) laid the foundation of archaeological knowledge, and was continued by him in Les Monuments de la monarchie française, 1729-1732. Both these works have been translated into English. Montfaucon’s Bibliotheca bibliothecarum manuscriptarum (1739) is a list of the works in MS. in the libraries with which he was acquainted.

A list of his works will be found in Bibliothèque des érudits de la congrégation de Saint-fout, by C. de Lame (1882), and in the article in the Nouvelle biographie générale, which gives an account of their scope and character; see also Emmanuel de Broglio, La Société de l’abbaye de St-Germain-des-Prés au 18e siècle: Bernard de Montfaucon et les bernardinis (5 vols., Paris, 1891).

MONTFERRAT, COUNT OF, a title derived from a territory south of the Po and east of Turin, and held by a family who were in the 12th century one of the most considerable in Lombardy. In 1147 a count of Montferrat took part in the Second Crusade; but the connexion with the Holy Land begins to be intimate in 1176. In that year William Longsword, eldest of the five sons of Count William III., came to the kingdom of Jerusalem, on the invitation of Baldwin IV. and the baronage, and married the heiress of the kingdom, Sibylla. He died within a few months; but his wife bore a posthumous son, who became Baldwin V. Count William III. himself (uncle to Philip of France and brother-in-law to Conrad III.) afterwards came to the Holy Land to watch over the interests of his grandson; and he was among the prisoners taken by Saladin at Hittin in 1187. Shortly after the battle of Hittin there appeared in Palestine the ablest and most famous of the family, Count William’s second son, Conrad, following the family tradition, and invited by the emperor Isaac Angelus, had gone to serve at the court of Constantinople. He soon became a considerable person; married Isaac’s sister, and defeated and killed a usurper; but he was repaid by ingratitude and suspicion, and fled from Constantinople to Palestine in 1187. Putting into ‘Tyre he was able to save the city from the deluge of Mahommedan conquest, which sealed Saladin’s victory at Hittin. He afterwards raised himself in 1210, and returned to Jerusalem (Guy, the king of Jerusalem); and from it he both sent appeals for aid to Europe—which largely contributed to cause the Third Crusade—and despatched reinforcements to the crusaders, who, from 1188 onwards, were engaged in the siege of Acre. His elder brother had been the husband of the heiress Sibylla; and on the death of Sibylla, who had carried the crown to Guy de Lusignan by her second marriage, Conrad married her younger sister, Isabella, now the heiress of the kingdom, and claimed the crown (1190). The struggle between Conrad and Guy paralysed the energies of the Christians in 1191. While Richard I. of England espoused the cause of Guy, who came from his own county of Poitou, Philip Augustus espoused that of Conrad. After the departure of Philip, Conrad fomented the opposition of the French to Richard, and even intrigued with Saladin against him. But he was the one man of ability who could hope to rule the debris of the kingdom of Jerusalem with success; he was the master of an Italian statecraft which gave him the advantage over his ingenuous rival; and Richard was finally forced to recognize him as king (April 1192). In the very hour of success, however, Conrad was struck down by the emissaries of the Old Man of the Mountain (the chief of the Assassins).

Still another son or Count William III. achieved distinction. This was Boniface of Montferrat, the younger brother of Conrad, who was chosen leader of the Fourth Crusade in 1201, on the death of Theobald of Champagne. In the winter of 1201-1202 he went to Germany to visit Philip of Swabia; and there it has been suggested, he arranged the diversion of the Fourth Crusade to Constantinople (see CRUSADES). Yet in the course of the crusade he showed himself not unsympathetic to Innocent III., who was entirely opposed to such a diversion. After the capture of Zara, however, he joined the crusaders, and played a great part in all the events which followed till the capture of Constanti napole on the Latins in 1204. But Baldwin of Flanders was elected emperor over his head; and his irritation was not wholly allayed by the grant of Macedonia, the north of Thessaly, and Crete (which he afterwards sold to Venice). In 1207 he died, killed in battle with the Bulgarians. He left a son Demetrius, who assumed the title of king of Thessalonica, which the father had never borne (cf. Luchoir, Innoceint III.: La question d’Orient, p. 190). In 1222 Demetrius lost his kingdom to Theodore Angelus, and the house of Montferrat its connexion with the East.

See Savio, Studi storici sul marchese Guglielmo III. di Montferrat (Turin, 1882); Ilgen, Markgraf Konrad von Montherat (1880); and also the works of Cerrato (Turin, 1884) and Desimoni (Genoa, 1880).

MONTFLEURY (d. 1667), French actor, whose real name was Zacharie Jacob, was born in Anjou during the last years of the 16th century. He was enrolled as one of the pages to the duc de Guise, but he ran away to join some strolling players,
assumed the name of Montfleury. About 1635 he was a valued member of the company at the Hôtel de Bourgogne, and he was in the original cast of the Cid (1656) and of Horace (1649). Richelieu thought highly of him, and when in 1638 Montfleury married the actress Jeanne de la Chalpe (d. 1683), the cardinal desired the ceremony to take place at his own country house at Rueil. Montfleury died in Paris from the rupture of a blood-vessel, while playing the part of Orestes in Andromaque, in December 1667. He was the author of a tragedy, La Mort d'Asdralob, performed in 1647.

MONTFORT, the name of a famous French family long seated at Montfort l’Amaury, near Paris, descended from a certain William, a descendant of the counts of Flanders, who flourished during the latter part of the 10th century, and who built a castle at Montfort l’Amaury. Until 1209, when Simon IV. took the title of count, William and his successors were known as barons de Montfort. This Simon IV. de Montfort (c. 1160-1218), a son of Simon III. (d. 1181), is chiefly known for the very active part which he took in the crusade against the Albigenses. Twice he went to Palestine as a crusader, and in 1209, answering the call of Pope Innocent III., he joined the host which was sent to the aid of the crusaders of Toulouse. He became viscomte de Béziers and of Carcassonne, and was soon the leader of the crusaders. He took place after place, defeated Raymond VI., count of Toulouse, at Castelnaudary, and about a year later (September 1213) gained a victory over Raymond’s ally, Peter II., king of Aragon, under the walls of Muret. Simon then turned his attention to administering and organizing Languedoc. After a lively discussion in the Lateran Council of 1215, the pope, somewhat reluctantly, confirmed him in the possession of the greater part of the lands of the count of Toulouse, and after two more years of warfare he was killed while besieging the city of Toulouse on the 25th of June 1218.

The count’s eldest son, Amaury de Montfort (1192-1241), was unable to hold his own, although Philip Augustus sent some troops to his assistance in 1222. He abandoned his interests in the south of France in favour of the new king Louis VIII., and in 1239 he went on crusade to the Holy Land, dying soon afterwards at Otranto. In 1238 Amaury was made constable of France. Simon IV. had a brother, Guy de Montfort (d. 1228), who shared his military exploits both in Asia and in Europe, and who was afterwards employed by Louis VIII. to negotiate with the pope at Rome. He was killed before Vareilles on the 31st of January 1228. In 1204 Yolande (d. 1222), the heiress of the Montforts, married Arthur II., duke of Brittany, and the county of Montfort became part of this duchy. Their son, John, count of Montfort, claimed Brittany in opposition to Charles, count of Blois, and at length secured the duchy. Except for one interval his descendants held it until it was united with the French crown at the end of the 15th century.

See A. Molinié, Catalogue des actes de Simon et d’Amaury de Montfort (1873); and C. Duval, La Soumission de la vicomté de Carcassonne par Simon de Montfort et la croisade contre Raimond VI. (1884).

MONTFORT, SIMON DE, EARL OF LEICESTER (d. 1265), English statesman and soldier, was born in France about the year 1200. He was the fourth and youngest son of Simon IV. de Montfort (see above), the leader of the Albigensian crusade, by Alicia de Montmorenci. Simon IV., whose mother was an heiress of the Beaumont family, claimed in her right, and received from King John, the earldom of Leicester (1207), only to lose it again through espousing the French side in the wars between that sovereign and Philip Augustus. The young Simon, of whose youth and education nothing is recorded, came to England in 1230 and attached himself to Henry III., obtaining with the consent of his sole surviving brother Amaury a re-grant of the family earldom. Simon was for a time unpopular with the English and closely attached to the royal party. He gave, however, an early proof of religious fervour, and of an unbounding harshness, by the expulsion of all the Jews who had settled in his borough of Leicester to practise usury. In 1238 he obtained the hand of the king’s sister Eleanor, the widow of the younger William Marshal. The king approved of the match, but it was resisted by his brother Richard of Cornwall and the baronage, and objections were raised on the ground that Eleanor had previously taken vows of chastity. With some difficulty Earl Richard was pacified; and Montfort obtained the pope’s confirmation of the marriage by a personal visit to Rome. In 1239, however, the influence of detractors and a quarrel over some obscure financial transactions in which he appears to have used Henry’s name without a formal warrant led to a breach between himself and the king. The earl and his wife went for a time to France; and, though a nominal reconciliation with the king was soon effected, both departed on crusade with Richard of Cornwall in 1240. Eleanor was left behind in Apulia while her husband proceeded to the Holy Land. He acquitted himself with distinction, and there was some thought among the Frankish barons of appointing him to act as regent of the Latin kingdom of Jerusalem. But he returned in 1241, took part in Henry’s disastrous French expedition of 1242, and was readmitted to full favour. Between 1243 and 1248 he received many gifts from the king; he stood forward in parliament as a mediator between the court and the discontented nobles; and he was one of the champions of his friends Grosseteste and Adam de Marsh that we learn of his dissatisfaction with the condition of church and state. He was keenly interested in Grosseteste’s proposals for ecclesiastical reformation, and was considered the mainstay of the reforming party. In 1248 he again took the cross, with the idea of following Louis IX. to Egypt. But, at the repeated requests of the king and council, he gave up this project in order to act as governor in the unsettled and disaffected duchy of Gascony. Bitter complaints were excited by the rigour with which the earl suppressed the excesses of the seigneurs and of contending factions in the great communes. Henry yielded to the outcry and instituted a formal inquiry into the earl’s administration. Montfort was formally acquitted on the charges of oppression, but his accounts were disputed by the king, and he retired in disgust to France (1252). The nobles of France offered him the regency of the kingdom, vacant by the death of the queen—mother Blanche of Castile, but he preferred to make his peace with Henry (1253), in obedience to the exhortations of the dying Grosseteste. He helped the king in dealing with the dissatisfaction of Gascony; but their reconciliation was a hollow one, and in the parliament of 1254 the earl led the opposition in resisting a demand for a subsidy. In 1256 and 1257, when the discontent of all classes was coming to a head, Montfort nominally adhered to the royal cause. He undertook, with Peter of Savoy, the queen’s uncle, the difficult task of extricating the king from the pledges which he had given to the pope with reference to the crown of Sicily; and Henry’s writs of this date mention the earl in friendly terms. But at the “Mad Parliament” of Oxford (1258) Montfort appeared side by side with the earl of Gloucester at the head of the opposition. It is said that Montfort was reluctant to approve the oligarchical constitution created by the Provisions of Oxford, but his name appears in the list of the Fifteen who were to constitute the supreme board of control over the administration. There is better ground for believing that he disliked the narrow class-spirit in which the victorious barons used their victory, and that he would gladly have made a compromise with the moderate royalists whose policy was guided by the Lord Edward, Henry’s eldest son. But the king’s success in dividing the barons and in fostering a reaction rendered such projects hopeless. In 1261 Henry revoked his assent to the Provisions, and Montfort left the country in despair.

He returned in 1263, at the invitation of the barons, who were now convinced of the king’s hostility to all reform; and raised a rebellion with the avowed object of restoring the form of government which the Provisions had ordained. For a few weeks it seemed as though the royalists were at his mercy; but he made the mistake of accepting Henry’s offer to abide by the arbitration of Louis IX. of France. At Amiens, in January 1264, the French king decided that the Provisions were unlawful and
invalid. Montfort, who had remained in England to prepare for the worst, at once resumed the war, and thus exposed himself to a charge of pettifoggery, from which he can only be defended on the hypothesis that he had been led to hope for a genuine compromise. Though merely supported by the towns and a few of the younger barons, he triumphed by superior generalship at Lewes (May 14, 1264), where the king, the Lord Edward, and Richard of Cornwall fell into his hands. Montfort used his victory to set up the government by which his reputation as a statesman stands or falls. The weak point in his scheme was the establishment of a triumvirate (consisting of himself, the young earl of Gloucester, and the bishop of Chichester) in which his colleagues were obviously figureheads. This flaw, however, is mitigated by a scheme, which he simultaneously promulgated, for establishing a thorough parliamentary control over the executive, not excepting the triumvir. The parliament which he summoned in 1265 was, it is true, a packed assembly; but it can hardly be supposed that the representation which he granted to the towns (see Parliament and Representation) was intended to be a temporary expedient. The reaction against his government was baronial rather than popular; and the Welsh Marchers particularly resented Montfort's alliance with Llewellyn of North Wales. Little consideration for English interests is shown in the treaty of Pipton which sealed that alliance (June 22, 1265). It was by the forces of the Marchers and the strategy of Edward that Montfort was defeated at Evesham (Aug. 4). Divided from the main body of his supporters, whose strength lay in the east and south, the earl was outnumbered and surrounded before reinforcements could reach him. For years after his death he was revered by the commons as a martyr, and the government had no little difficulty in reducing the remnants of his baronial supporters. His character has suffered in the past from indiscriminate eulogy as much as from detractive letters of Adam de Marsh in J. W. Crocker's Monasticon Anglicanum, vol. i (Rolls series, 1858); H. R. Luard, Epistolae Roberti Grosseteste (Rolls, series, 1886); F. S. Stevenson, Robert Grosseteste (London, 1899); W. H. Blaauw, The Barons' War (Cambridge, 1871). (H. W. C. D.)

MONTGAILLARD, JEAN GABRIEL MAURICE ROQUES, COMTE DE (1761-1841), French political agent, was born at Montgaillard, near Villefranche (Haute Garonne), on the 26th of November 1761. His parents belonged to the minor nobility, and he was educated at the military school of Sorèze, where he attracted the notice of the comte de Provence (afterwards Louis XVIII.). After serving for some years in the West Indies Maurice de Roques returned to France. In 1789 he was established in Paris as a secret diplomatic agent, and though he emigrated to England after the 9th of August 1792, he returned six weeks later to Paris, where his security was most probably purchased by services to the revolutionary government. He was again serving the Bourbon princes when he met Francis II. of Austria at Vypes in 1794 and saw Pitt in London, where he published his État de la France au mois de mai 1794, predicting the fall of Robespierre. He was employed by Louis XVIII. to secure Austrian intervention on behalf of Mme Royale (afterwards duchess of Angoulême), still a prisoner in the Temple, and he drew up the proposition made by the prince to Charles Pichéru, the details of which appear in his Mémoires sur la trahison de Pichéru (Montpellier, April 18, 1840). In June 1796 he made a journey to Italy in the hope of opening direct relations with Bonaparte. On his return to the princes at Blankenburg he was regarded with suspicion, and he departed for Paris to await events. He is thought to have indicated the possession by the comte d'Antraigues, agent of the princes, of documents compromising Pichéru. In April 1798 he surrendered to Claude Roberjot, the Hamburg minister of the Directory, further papers relating to the matter. He followed Roberjot to Holland, and there wrote a memorandum to prove that the only hope for France lay in the immediate return of Bonaparte from Egypt, followed by assumption of the supreme power. This note reached Alexandria by way of Berlin and Constantinople. When he ventured to return to Paris in the hope of recognition from the First Consul he was imprisoned, and on his release he was kept under police supervision. Napoleon, who appreciated his real insight into European politics and his extraordinary knowledge of European courts, attached him to his secret cabinet in spite of his intriguing and mendacious character. He received a salary of 14,000 francs, reduced later to 6000, for reports on political questions for Napoleon's use, and for pamphlets written to help the imperial policy. He tried to dissuade Napoleon from the Austrian marriage and the Russian campaign, and counsels for the limitation of the empire within the Rhine, the Alps and the Pyrenees. The Bourbon restoration made no change in his position; he was maintained as confidential adviser on foreign and home politics, and gave shrewd advice to the new government. His career ended with the old monarchy, and he died in obscurity at Chaillot on the 8th of February 1841.

His Souvenirs, which must be read with the utmost caution, were edited by Clément de Lacroix (3rd ed., 1895); his Mémoires diplomatiques (1805-1819) were published by the same editor in 1806. His État de la France was translated into English by Edmund Burke. His other writings include: Ma conduite pendant le cours de la révolution française (London, 1795); Histoire secrète de Coblenz dans la révolution des français (London, 1795); De La France et de l'Europe sous le gouvernement de Bonaparte (Lyon, 1804); Situation de l'Angleterre en 1811 (Paris, 1812); Dés un retour de la monarchie des Bourbons et du retour à l'ordre (Paris, 1814); and Histoire de France depuis 1825 jusqu'à 1830 (Paris, 1839).

MONTGELAS, MAXIMILIAN JOSEF GARNERIN, COUNT VON (1759-1838), Bavarian statesman, came of a noble family in Savoy. His father John Sigmund Garnerin, Baron Montgelas, entered the military service of Maximilian Joseph III., elector of Bavaria, and married the countess Ursula von Trauner. Maximilian Joseph, their eldest son, was born on the 10th of September 1759. He was educated successively at Nancy, Strassburg and Ingolstadt. Being a Savoyard on his father's side, he naturally felt the French influence, which was then strong in Germany, with peculiar force. To the end of his life he spoke and wrote French more correctly and with more ease than German. In 1779 he entered the public service in the department of the censorship of books. The elector Charles Theodore, who had at first favoured him, became offended on discovering that he was associated with the Illuminati, the supports of the anti-clerical movement called the Aufklärung. Montgelas therefore went to Zweibrücken, where he was helped by his brother Illuminati to find employment at the court of the duke, the head of a branch of the Wittelsbach family. From this refuge also he was driven by orthodox enemies of the Illuminati. The brother of the duke of Zweibrücken—Maximilian Joseph—took him into his service as private secretary. When his employer succeeded to the duchy Montgelas was named minister, and in that capacity he attended the conference of Rastadt in 1798, where the reconstruction of Germany, which was the consequence of the French Revolution, was in full swing. In 1799 the duke of Zweibrücken succeeded to the electorate of Bavaria, and he kept Montgelas as his most trusted adviser. Montgelas was the inspirer and director of the policy by which the electorate of Bavaria was turned into a kingdom, and was very much increased in size by the annexation of church lands, townships and small lordships. As this end was achieved by undeviating servility to Napoleon, and the most cynical disregard of the rights of Bavaria's German neighbours, Montgelas became the type of an unpatriotic politician in the eyes of all Germans who revolted against the supremacy of France. From his own conduct and his written defence of his policy it is clear that such sentiments as theirs appeared to be merely childish to Montgelas. He was a thorough politician of the
18th-century type, who saw and attempted to see nothing except that Bavaria had always been threatened by the house of Habsburg, had been supported by Prussia for purely selfish reasons, and could look for useful support against these two only from France, who had selfish reasons of her own for wishing to counterbalance the power both of Austria and Prussia in Germany. As late as 1813, when Napoleon's power was visibly breaking down, and Montgelas knew the internal weakness of his empire well enough to visit Paris, he still continued to maintain that France was necessary to Bavaria. The decision of the king to turn against Napoleon. 1814 was taken under the influence of his son and of Marshal Wrede rather than of Montgelas, though the minister would not have been influenced by any feeling of sentimentality to adhere to an ally who had ceased to be useful. In internal affairs Montgelas carried out a policy of securitization and of administrative centralization often by brutal means, which showed that he had never wholly renounced his opinions of the time of the Enlightenment movement. His enemies persuaded the king to dismiss him in 1817, and he spent the remainder of his life in retirement till his death in 1838. He had married the countess von Arco in 1803, and had eight children; in 1809 he was made a count.

See Denkwürdigkeiten des bayr. Staatsministers Maximilian Graf von Montgelas, a German version of the French original, ed. by Louis Graf von Montgelas (Stuttgart, 1857); Biographical notice in Der Gartenmeister (1853); Dumoulin Eckart, Bayern unter dem Ministerium Montgelas (Munich, 1894).

MONT GÉNÈVE—MONTGOMERY, J., 783

being due to the fact that sections of the poem were written at different times—on Youth's choice between a richly laden cherry-tree on a high crag and a sloe 'bush' at his feet. His other poems are: The Flying between Montgomery and Poltaw (1629; 1st ed., 1621) which reproduces the literary habit of the Flying of Dunbar and Kennedy; a series of 70 sonnets, a large number of miscellaneous poems, amatory and devotional; and The Minde Melodie, Contayning certayne Psalms of the Kinglie Prophete Davyd, aplied to a new pleasant tune (Edinburgh, 1605). The formal value of Montgomery's verse was fittingly acknowledged by James VI. in his early critical essay Ane Schort Treaite containing some reuils and cautelus to be observd and eschew into Scottis Poesie, where the author makes three quotations from Montgomery's poems, then in circulation in manuscript. Montgomery had written a sonnet to his majesty, which is prefixed to the Essays of a Pretense.

Montgomery stands apart from the courtier-poets Ayton, Stirling, and others, who write in the literary English of the South. He carries on the Middle Scots tradition, and was not without influence in the vernacular revival, in Allan Ramsay and his successors.

MONTGOMERY, GABRIEL, SEIGNEUR DE SORGES, COMTE DE (c. 1530–1574), French soldier, became a lieutenant in the king of France's Scottish garrison of which his father was captain, and eventually took him to France which inadvertently caused the death of King Henry II. in a tournament (June 30, 1559) he was disgraced and retired to his estates in Normandy. He studied theological questions and espoused the cause of the Reformers. In 1562 he allied himself with the prince of Condé, took Bourges, and defended Rouen from September to October 1562 against the royal army. In the third War of Religion he occupied Béarn and Bigorre (1566). Escaping from the massacre of Massacre-road mounts in 7 m. from Briançon, at the very head of the Durance valley, to the pass. On the French side of the divide is the village of Bourg Mont Génèvre, and on the Italian side that of Clavières, both inhabited all the year round, as the pass runs east and west, and is thus sheltered from the north wind. A descent of 5 m. leads down to Césans in the Doria Riparia valley, which is followed for 5 m. more to Oulx (17 m. from Briançon), on the Mon Cenis railway.

MONTGOMERY, ALEXANDER (c. 1599–c. 1610), Scottish poet, was the second son of Hugh Montgomery of Hessilhead, Ayrshire, and was born about the middle of the 16th century. He spent some part of his youth in Argyleshire and afterwards lived for a time at Compton Castle, in Galloway. He was in the service of the regent Morton; thereafter, on the regent's demise of office in 1578, in that of the king, James VI. In 1583 the grant by the Crown of a pension of 500 marks was confirmed; and three years later he set out on a tour through France, Flanders and other countries. He appears to have got into trouble, to have been imprisoned abroad, and to have lost favour at the Scottish court, and (for a time) his pension. We have no record of his closing years.

Montgomery's chief poem is the Cherry and the Sloe, first printed in 1597 (two impressions). It was frequently reprinted in the 17th and 18th centuries, and appeared twice in Latin guise in 1631, in Demottis' Centum et sylvestre prunum, opus poëmaticum (Stuttgart, 1759), included in the collected edition of Montgomery's Poems, by David Irving (1821), and by James Cranston, for the Scottish Text Society (1882). The text in the latter is a composite of 930 lines from the second impression of 1597 (Iv. I. 398) and 766 lines from the version in Allan Ramsay's (ed.) Ever Green (1724); but a better text, from a MS. in the Laing collection in the university of Edinburgh, has been prepared (1907) for the Scottish Text Society by Mr George Stevenson. The poem, written in the complicated alliterative fourteen-lined stanza, is a confused allegory—the confusion

1 Alexander's brother, Robert Montgomery (d. 1609), was made bishop or archbishop, of Glasgow, in 1581, an appointment which was strongly objected to by the General Assembly. The long struggle which ensued was only terminated by Montgomery's resignation of the see in 1587.

See L. Marlet, Le Comte de Montgomery (Paris, 1890).

MONTGOMERY, JAMES (1777–1854), British poet and journalist, son of a Moravian minister, was born on the 4th of November 1771, at Irvine in Ayrshire, Scotland. Part of his boyhood was spent in Ireland, but he received his education in Yorkshire, at the Moravian school of Fulneck near Leeds. He edited the Sheffield Iris for more than thirty years. When he began his career the position of a journalist who held pronounced views on reform was a difficult one, and he twice suffered imprisonment (in 1795 and 1796). His Wanderer of Switzerland (1806), describing the French occupation, attracted considerable attention. The author was described by Lord Byron in a footnote to English Bards and Scotch Reviewers, as "a man of considerable genius," whose Wanderer of Switzerland was worth a thousand "Lyrical Ballads." The book had been mercilessly ridiculed by Jeffrey in the Edinburgh Review (1807), but in spite of this Montgomery achieved a wide popularity with his later volumes of verse: The West Indies (1810); The World Before the Flood (1812); Greenland (1810); Songs of Zion (1822); The Pelican Island (1826). On account of the religious character of his poetry, he is sometimes confounded with Robert Montgomery, very much to the injustice of his reputation. His verses were dictated by the inspiring force of humanitarian sentiment, and he was especially eloquent in his denunciation of the slave trade. The influence of Campbell is apparent in his earlier poems, but in the Pelican Island, his last and best work as a poet, he evidently took Shelley as his model. His reputation now rests chiefly on his hymns, about a hundred of which are still in current use. His Lectures on Poetry and General Literature (1833) show considerable breadth of sympathy and power of expression. A pension of
Montgomery, R.—Montgomery

£150 was bestowed on him by Sir Robert Peel in 1835. He died at Sheffield on the 30th of April 1854.

His poems were collected and edited by himself in 1841. The volumes, Monty, published in seven volumes (1856-1858) by John Holland and James Everett, contain valuable information on English provincial politics.

Montgomery, Richard (1736-1775). American soldier, was born in Co. Dublin, Ireland, in 1736. Educated at St Andrew's and at Trinity College, Dublin, he entered the British army in 1756, becoming captain six years later. He saw service at Louisbourg in 1757 and in the Lake Champlain expedition of 1759, and as adjutant of his regiment (the 17th foot) he shared in the final threefold advance upon Montreal. Later he was present at Martinique and Havana. In 1772 he left the army, settled in New York, and married a daughter of Robert R. Livingston. Three years later he was a delegate to the first provincial congress of New York, and became brigadier-general in the Continental army. He was sent with Schuyler on the Canadian expedition, and, on Schuyler's falling ill, the command devolved upon him. Hampered by the inclemency of the season and the gross indiscretion of the troops, he went forward, gaining a few minor successes and capturing the colours of the 7th (Royal) Fusiliers, and met Benedict Arnold's contingent at Point aux Trembles. They pushed on to Quebec barely 800 strong, but an assault was made on the 31st of December 1775, and almost at the first discharge Montgomery was killed. The body of the American general was honourably interred by the Quebec garrison. Congress caused a memorial to be erected in St Paul's church, New York, and in 1818 his remains were conveyed thither from Quebec.

Montgomery, Robert (1807-1855), English poet, natural son of Robert Gomy, was born at Bath in 1807. He was educated at a private school in Bath, and founded an unsuccessful weekly paper in that city. In 1828 he published The Omniscient Deity, which hit popular religious sentiment so exactly that it ran through eight editions in as many months. In 1830 followed The Puff add (a satire), and Satan. An exhaustive review in Blackwood by John Wilson, followed in the thirty-first number by a burlesque of Satan, and two articles in the first volume of Fraser, ridiculed Montgomery's pretensions and the excesses of his admirers. But his name was immortalized by Macaulay's famous onslaught in the Edinburgh Review for April 1830. As a poet, he deserved every word of Macaulay's severe censure, though the brutality of the attack cannot be defended. This exposure did not, however, diminish the sale of his poems; The Omniscience of the Deity reached its 8th edition in 1838. In 1830 Montgomery entered Lincoln College, Oxford, graduating B.A. in 1833 and M.A. in 1835. Taking holy orders in 1833 he obtained a curacy at Whittington, Shropshire, which he exchanged in 1836 for the charge of the church of St Jude, Glasgow. In 1843 he removed to the parish of St Peter's, London, where he was minister of Percy Chapel. He died at Brighton in 1855. He also wrote The Messiah (1822), Woman, the Angel of Life (1833), Oxford (1831), and many devotional and theological works.

Montgomery, a city of Alabama, U.S.A., the capital of the state and the county-seat of Montgomery county, situated (about 162 ft. above the sea) S.E. of the centre of the state, on the left bank of the Alabama river, which is here navigable. Pop. (1900), 30,346, of whom 17,229 were of negro descent and 666 were foreign-born; (1910, census), 38,136. Montgomery is served by the Louisville & Nashville, the Mobile & Ohio, the Atlantic Coast Line, the Seaboard Air Line, the Central of Georgia, and the Western of Alabama railways, and by freight steamers plying between Montgomery and Mobile. Among the public institutions are the capital, near which is a Confederate soldiers' monument (erected by the women of Alabama), the county court-house, the Federal building, the Carnegie library, the masonic temple and the First National Bank and Bell buildings. The public institutions include the city infirmary and St Margaret's hospital, the latter under the direction of the Sisters of Charity. The city has about 100 acres of parks, Oak Park being the most important. Situated in the "Cotton Belt" of Alabama, Montgomery handles 160,000,000 bales annually. Truck farming is an important industry. The Alabama state fair is held here annually. Among the manufactures are fertilizers, machine-shop products, cotton goods, lumber products, cigars, harness, beer, stone, and bricks. The value of the factory products in 1905 was $8,877,653 (an increase of 33.7% over that in 1900). The leading newspapers are the Montgomery Advertiser (morning) and the Montgomery Journal (evening).

The site of Montgomery was once occupied by an Indian village known as Ecunchatty. The first permanent white settlement was made in 1814 by Arthur Moore. In 1817 Samuel Dexter of Massachusetts laid out a town and named it New Philadelphia. In 1819 it was united with East Alabama Town, an adjoining settlement on the river, under the present name (in honour of General Richard Montgomery), and a third settlement, Alabama Town, later became a part of Montgomery. Montgomery was first incorporated in 1837. The place soon became the commercial emporium of the Alabama "Cotton Belt." In 1847 it became the capital of the state instead of Tuscaloosa. On the 7th of January 1861, the State Convention through which Alabama seceded from the Union met in the capitol; at the same place delegates from six states met, on the 4th of February, and organized the Confederate States of America. Montgomery was the capital of the new government (hence the popular name "Cradle of the Confederacy") until May 1861, when that honour was transferred to Richmond, Virginia. It was the seat of Confederate military factories, and on the 12th of April 1865 it was captured by Federal troops. Montgomery received a new city charter in 1905.

Montgomery, a town and district of British India, in the Lahore division of the Punjab. The town has a station on the North-Western railway about half-way between Lahore and Multan. Pop. (1901), 600. A town was founded in 1854 on the opening of the railway, and called after Sir Robert Montgomery, then lieutenant-governor. It is situated in a desolate upland, and though not unhealthy is singularly comfortless.

The District of Montgomery lies in the Bari Doab, or tract between the Sutlej and the Ravi, extending also across the latter river. Area, 4771 sq. m. In the former tract a fringe of cultivated lowland skirts the bank of either river, but the whole interior upland consists of a desert plateau partially overgrown with brushwood and coarse grass, and in places with impenetrable jungle. On the farther side of the Ravi, again, the country at once assumes the same desert aspect. The population in 1901 was 463,168, showing an apparent decrease of 0.4 % in the decade due to emigration to the Chenab Colony. The principal crops are wheat, pulse, cotton and fodder. Camels are bred for export. The leading manufactures are of cotton and silk, and the manufacture of cloth, and there are factories for ginning and pressing cotton. The district is traversed by the main line of the North-Western railway, from Lahore to Multan, and is irrigated by the Upper Sutlej irrigation canal system, and also from the Ravi.

From time immemorial the Rechna Doab has formed the home of a wild race of pastoral Jats, who have constantly maintained a sturdy independence against the successive rulers of northern India. The sites of Kot Kamalia and Harappa contain large mounds of antique bricks and other ruins, while many other remains of ancient cities or villages lie scattered along the river bank, or dot the now barren stretches of the central waste. The pastoral tribes of this barren expanse do not appear to have paid more than a nominal allegiance to the Moslem rulers, and even in later days, when Ranjit Singh extended the Sikh supremacy as far as Multan, the population of the most part remained in a chronic state of rebellion. British influence was first exercised in the district in 1847, when an officer was deputed to effect a summary settlement of the land revenue. Direct British rule was effected on the annexation of the Punjab in 1849. There was a remarkable rising of the wild clans during the Mutiny of 1857, several actions being fought before order was restored.
MONTGOMERY—MONTH

MONTGOMERY (Tre Faldwyn), a municipal and parliamentary borough, market town, and the county town of Montgomeryshire, Wales, situated on a wooded hill near the east bank of the Severn, 7 m. S. of Welshpool (Cambrian railway). Pop. (1901), 1034. The principal feature of the town is the ruined castle. Not far off are the traces of an extensive British fort, and, about a mile east, the line of Offa's Dyke, forming the Shropshire boundary. The borough was incorporated by Henry III., when the castle was enlarged, and was the scene of frequent contests between that king and Llewelyn the Great. In the 14th century the castle was held by the Mortimers, from whom it passed to the Yorkists. The Crown gave it, in the 15th century, to the Herberts of Cherbury, one of whom, in 1644, surrendered it to the Parliamentarians, who dismantled it.

MONTGOMERYSHIRE (Welsh Swydd Tre Faldwyn, Baldwyn's town shire), a county of Wales, bounded N. by Denbigh, N.E. and E. by Shropshire, S. by Radnor and Cardiganshire, and W. and N.W. by Merioneth. Its length from S.E. to N.W. is about 30 m.; N.E. to S.W. it measures about 35 m. The surface is broken, though the highest hills are only round the county borders—to the north Berwyn (stretching into Denbighshire); to the south-west Plinlimmon (q.v.); east, the Breidden hills; south, the Kerry hills. The principal rivers and streams are: the Severn, flowing east and north; the Wye, farther south; the Dyfi, Vyrnwy (Fyrnwy), Clywedog, Tanat and Rhinog. Except the Wye and Dyfi, the principal streams are tributaries of the Severn. Lake Vyrnwy, formed in 1888, is the chief water-supply of Liverpool. The Montgomeryshire canal, some 24 m. long, is connected with the Shropshire Union and Ellesmere canals. The county was formerly a recognized source of oak timber for the navy.

Geologically, the county is occupied almost exclusively by Ordovician and Silurian rocks. The latter, mainly Wenlock beds, bordered by a fringe of Llandovery rocks, lie in the form of a complex syncline down the centre of the county from a few miles north of Oswestry through Llangadfan, Llanfyllin, Llanfair, Welshpool, Montgomery and Newtown. The boundary is very irregular. Between Newtown and Kerry hill Ludlow beds come in, and on the edge of the forest of Clun the Old Red Sandstone just crosses the boundary. This county lies north and south of the Silurian tracts Ordovician rocks occupy the remaining area: they contain bands of anesite and felsite in the Berwyn hills, also large areas west of Clun. In the last-named hill there is a large laccolithic mass of dolerite and a similar rock occurs at Criggion. At Machynlleth slate is worked in the Ordovician, and numerous metallic ores are found in the neighbourhood of Newtown from which lead, silver and zinc are obtained. Glacial deposits are prevalent over much of the county.

The climate is mild, and the soil generally fertile, especially in the Severn valley, though towards Merionethshire there are rough moors. The average annual rainfall is about 50 inches, and tends to diminish. The hardy, small, mountain pony is still to be found here. Hunters and cart-horses are bred. Sheep-breeding is practised, and Shropshire downs aresuperseding the little clunis. Of the relatively few green crops potatoes are the most important; oats are the principal grain. Permanent pasture covers a large area. Hill pasture is also extensive. Woollen cloth and flannel manufacture have revived considerably.

The Cambrian railway, entering Montgomeryshire in the north-east, by Llanymynech, crosses it to the south-west with branches to Llanfyllin, Westbury and Van. There is also a branch from Caersws to Glyndyfr (Glandovey) junction, with the coastwise branch of the same company.

The area of the ancient and administrative counties is 510,112 acres, or 797 sq. m., with a population of 40,562 in 1901. Many of the towns, like Welshpool, Newtown, and Llanblethen, are everywhere the favourite speech. The county returns one member to parliament, and includes the Montgomery district of parliamentary boroughs: Llanfyllin (pop. 1632), Llanidloes (2770), Montgomery (1034), Machynlleth, Newtown and Welshpool (6121). The first three and last of these are municipal boroughs. The urban districts are: Newtown and Llanllwychaen (6500), and Machynlleth (2038). The county is in the north Wales and Chester circuit, assizes being held alternately at Newtown and Welshpool.

Welshpool borough has a separate commission of the peace, but no separate court of quarter sessions. The ancient county (in Bangor, Hereford, and St Asaph dioceses) has 59 ecclesiastical parishes or districts, with parts of 11 others.

History and Antiquities.—The Welsh name of Baldwyn's town shire is taken from a Norman who gave homage to William the Conqueror for this division of Wales. The English name is from Roger de Montgomery, earl of Shrewsbury (temp. William Rufus). At the coming of the Romans this county was part of the Orдовices' territory (Britanniæ secunda), and there are remains of Roman encampments and fortifications at Caersws, Mathrafal, and near Montgomery. The roads connecting these stations can often be traced. Vestiges of a Roman camp are visible near Welshpool. Machynlleth was perhaps the Roman Magonia. Remains of old British camps are to be seen at Dolardddwy, on Breidden hill and at Caereinion. There are many cairns and barrows. Crossing the county was the Via Devana, joined by other roads. From the Roman evacuation under Flavius Honorius (d. A.D. 423) little is known of Montgomery until Wales was subdivided into three districts at the death of Rhodri Fawr, when Montgomery was included in Powys (Powys Gwynywuyyn, Upper Powys). Powys Castle was founded in 1108. About the end of the 11th century, probably, was built Baldwyn's Castle, taken later by the Welsh and retaken by Roger de Montgomery. In 1345 Roger Mortimer held it. At Carno, 11 m. from Newtown and 17 from Machynlleth, a battle decisive of North Wales sovereignty was fought in 946, and in 1081 the rightfull heir, Gruffydd ab Cynan, together with Rhys ab Tudur, prince of South Wales, here killed in battle Trawona ab Caradoc, the usurper, and most of his men. At Machynlleth is seen Owen Glendower's senate house (1402) where he was crowned prince of Wales.

MONTH (a common Teutonic word, cf. Ger. Mond, Du. maand, Dan. måned, &c., and cognate with Lat. mensis, Gr. μήν, &c., in other branches of the Indo-Germanic family; all ultimately from the root seen in the word for the moon in nearly all those languages), originally the period between two returns of the new moon; generally called a lunar and sometimes a synodic or illuminative month. The anomalistic month is the mean time taken by the moon in passing from one perigee to the next; the sidereal month is the mean time in which the moon makes a circuit among the stars; the tropical month is the mean time in which the moon traverses 360° of longitude; the nodical or draconic month is the mean time taken by the moon in passing from one rising node to the next; the solar month is one-twelfth of a tropical year. The lengths of the various months are: synodic = 29'5059 days; anomalistic = 27'53460; sidereal = 27'32156; tropical = 27'23228; solar = 27'03685. (For the calendar months see Calendar.)

In a law a month may mean either a lunar month, that is, a period of twenty-eight or twenty-nine days, or a civil calendar month. At common law, "month" generally means a lunar month, although in mercantile matters it has been generally understood to mean a calendar month, but there is no general exception giving that meaning in commercial documents. It can only have that meaning where according to the ordinary rules of construction a secondary meaning can be admitted (Brunner v. Moore, 1904, 1 Ch. 305). In bills of exchange or promissory notes a month means a calendar month (Bills of Exchange Act, 1882, s. 14 [4]). Where a servant is engaged subject to a month's notice or payment of a month's wages month is interpreted as a calendar month (Gordon v. Foster, 1 F. & F. 644). In acts specially interpreted, means lunar month, but in all acts passed since that date, month, unless words be added showing that lunar month was intended, means calendar month (Interpretation Act 1889, s. 3). In the rules of the supreme court and in the county court rules month means a calendar month. In mercantile contracts in computing the period of a month the day from which the time is to begin to run is excluded, but in sentences of imprisonment the day on which the sentence begins is included, so that the numerically corresponding
day in the month in which the sentence expires would be excluded.

MONTOLON, CHARLES TRISTAN, MARQUIS DE (1782-1853), was born at Paris. He was trained for a military career, and in his tenth year shared in the expedition of Admiral Truguet to the coast of Sardinia. Entering the army in 1788, he rose with rapidity and avowed himself, when chef d’escadron in Paris at the time of the coup d’etat of Brumaire (November 1799), entirely devoted to Bonaparte. He served with credit in the ensuing campaigns, and distinguished himself at the battle of Aspern-Essling (May 1809) where he was wounded. At the end of that campaign on the Danube he received the title of count and remained in close attendance on Napoleon, who confided to him several important duties, among others, a mission to the Archduke Ferdinand at Würzburg. At the time of the first abdication of Napoleon at Fontainebleau (April 11, 1814), Montholon was one of the few generals who advocated one more attempt to rally the French troops for the overthrow of the allies. After the second abdication (June 22, 1815) he with his wife accompanied the emperor to Rochefort, where Napoleon and his friends finally adopted the proposal, which emanated from Count Las Cases, to enter the Bourbonist cause. Montholon afterwards, when the Bourbons were expelled from Spain, sailed with Gourgaud, de Montholon, and de Tocqueville in South America in 1823; he was a member of the British nation and surrenderer to H.M.S. “Bellerophon.” Montholon afterwards, at Plymouth, asserted that the conduct of Captain Maitland of the “Bellerophon” had been altogether honourable, and that the responsibility for the failure must rest largely with Las Cases. Montholon and his wife accompanied the ex-emperor to St. Helena. To Montholon chiefly, Napoleon dictated the notes on his career which form so interesting, though far from trustworthy, a commentary on the events of the first part of his life. Montholon is known to have despised and flouted Las Cases, though in later writings he acknowledged laud his services to Napoleon. With Gourgaud, who was no less vain and sensitive than himself, there was a standing feud, which would have led to a duel but for the express prohibition of Napoleon. Las Cases left the island in November 1816, and Gourgaud in January 1818; but Montholon, despite the departure of his wife, stayed on at Longwood to the end of the emperor’s life (May, 1821). In a letter written to his wife he admitted that Napoleon had died, though he afterwards encouraged the belief that death was due to a liver complaint aggravated by the climate and by the restrictions to which Napoleon was subjected. After that event Montholon and Bertrand became reconciled to Sir Hudson Lowe (q.v.); but this did not prevent him, on his return to France, from vilifying that much abused man. Colonel Basil Jackson found him very frank as to the politique de Longwood which aimed at representing Napoleon as a martyr, and Sir Hudson Lowe as his persecutor. Montholon admitted that an “angel from heaven as governor would not have pleased them.” Montholon had to spend many years in Belgium; and in 1840 acted as chief of staff “in the absurd ‘expedition’ conducted by Louis Napoleon from London to Boulogne. He was condemned to imprisonment at Ham, but was released in 1847; he then retired to England and published the Récits de la captivité de l’empereur Napoleon à St. Hélène. In 1849 he became one of the deputies for the Legislative Assembly under the Second French Republic. He died on the 21st of September 1853.

MONTH’S MIND, in medieval and later England a service and feast held one month after the death of anyone in his or her memory. Bede speaks of the day as commemorationes dies. These “Minding days” were of great antiquity, and were survivals of the Norse minne or ceremonial drinking to the dead. “Minning Days,” says Blount, “from the Saxon Lemynge, days which our ancestors called their Monthes mind, their Year’s mind and the like, being the days whereon their souls (after their deaths) were had in special rememberance, and some office or obsequies said for them, as Orbits, Dirges.” The phrase is still used in Lancashire. Elaborate instructions for the conduct of the commemorative service were often left in wills. Thus, one Thomas Windsor (who died in 1749) orders that “on my moneth’s mind there be a hundred children within the age of sixteen years, to say for my soul,” and candles were to be burned before the rood in the parish church and twenty priests were to be paid by his executors to sing Placebo, Dirige, &c. In the correspondence of Thomas, Lord Cromwell, one in 1536 is mentioned at which a hundred priests took part in the mass. Commemorative sermons were usually preached, the earliest printed example being one delivered by John Fisher, bishop of Rochester, on Margaret, countess of Richmond and Derby, in 1509.

MONTILLA, a town of southern Spain, in the province of Cordova, 32 m. S. of the city of Cordova, by the Cordova-Bobadilla railway. Pop. (1900), 13,603. The oil of the district is abundant and good; and it is the peculiar flavour of the pale dried and white of Montilla that gives its name to the sherry known as Amontillado. Montilla was the birthplace of “The Great Captian,” Gonzalo or Gonsalvo de Cordova (1452-1515), and contains the ruined castle of his father, Pedro Fernandez de Cordova.

MONTLOSIER, FRANÇOIS DOMINIQUE DE REYNAUD, COMTE DE (1755-1838), French publicist, was born at Clermont-Ferrand (Puy-de-Dôme) on the 16th of April 1755, the youngest of a large family belonging to the poorer nobility. He was returned in 1791 to the Constituent Assembly, where he sat on the Royalist side, and he emigrated on its dissolution in September 1791. He was received into the emigrant army at Coblenz after some protest against the Liberal leanings he had shown in the Assembly. After the cannonade of Valmy, he withdrew to Hamburg, and thence to London, where he avoided English society, moving exclusively among the French exiles. In his Courrier de Londres, published in London, he advocated moderation and the abandonment by the exiles of any idea of revenge. He was recalled to Paris in 1801, with permission to publish his paper in London. The Courrier de Londres suppressed, moreover, its editor being compensated by a comfortable sinecure in the ministry of foreign affairs. Next year he sold his pen to the government to edit the violent anti-English Bulletin de Paris. At Napoleon’s request he undertook an account of the ancient monarchy of France, which should serve as a justification for the empire. After four years’ labour Montlosier submitted his work to a specially appointed committee, by which it was rejected because of the stress laid on the feudal limitations of the royal authority. The work De la monarchie française . . . ou recherches sur les anciennes institutions françaises . . . et sur les causes qui ont amené la révolution . . . appeared in 1814 in three volumes, a fourth and supplementary volume in the next year containing a preface hostile to Napoleon. His views were no more acceptable to Louis XVIII. than they had been to the emperor, and he devoted himself to agriculture until he was roused by the clerical and reactionary policy of Charles X. His anti-clerical Mémoire à consulter sur un système religieux et politique (1826) rapidly passed through eight editions. He had no part in the revolution of 1830, but supported Louis Philippe’s government and entered the House of Peers in 1832. He died on the 9th of December 1838 at Blois. Ecclesiastical burial was denied him because he had refused to abjure his anti-clerical writings.

Among his works should be mentioned: Mémoires sur la révolution française, le consulat, l’empire, la restauration, et les principaux événements qui l’ont suivie (2 vols., 1829).

MONTLUC (or MONTLUC), BLAISE DE LASSARAN-MASSÉNÈME, SEIGNEUR DE (c. 1502-1577), marshal of France, was born about 1502, at the family seat near Condum in the modern department of Gers. He was the eldest son, and his family was a good one, but, like most gentlemen of Gascony, he had to
trust to his sword. He served first as a private archer and man-at-arms in Italy, with Bayard for his captain, fought all through the wars of Francis I, and was knighted on the field of Cérisoles (1544), to which victory he brilliantly contributed as adviser to the young duke of Enghien. Having apparently enjoyed no patronage, he was by this time a man of middle age. Thenceforward, however, his merits were recognized. His chief feat was the famous defence of Siena (1555), which he has told so admirably. When the religious wars broke out in France, Montluc, a staunch royalist, held Guyenne for the king. Henry III. made him in 1574 marshal of France, an honour which he had earned by nearly half a century of service and by numerous wounds. He died at Estillac near Agen in 1577. Montluc's eminence above other soldiers of his day is due to his Commentaires de Messire Blaise de Montluc (Bordeaux, 1592), in which he described his fifty years of service (1521-1574). This book, the "soldier's Bible" (or "breviary," according to others), as Henry IV. called it, is one of the most admirable of the many admirable books of memoirs produced by the unlearned gentry of France at that time. It is said to have been dictated, which may possibly account in some degree for the singular vivacity and picturinessness of the style.

The Commentaires are to be found conveniently in the collection of Michael de Printz, the publisher and editor of the Société de l'histoire de France, ed. by M. de Ruble (5 vols., 1865-1872). See Röstow, Militärische Biographien, v. i. (Zürich, 1858).

MONTLUÇON, a town of central France, capital of an arrondissement, and the most important industrial centre in the department of Allier. Pop. (1906), 31,888. It is situated on the Cher, 50 m. S.W. of Moulins by the Orléans railway. The upper town, on an eminence on the right bank, consists of steep, narrow, winding streets, and preserves several buildings of the 15th and 16th centuries; the lower town, traversed by the Cher, is the seat of the industries, which embrace the manufacture of glass, chemicals, mirrors, sewing-machines, and iron and steel production. The Commentry coal-mines and Néris, a town with thermal springs, are a few miles distant to the south-east. Of the churches, Notre-Dame is of the 15th century, St Pierre partly of the 12th and St Paul modern. The town-hall, with a library, occupies the site of an old Ursuline convent, and two other convents are used as college and hospital. Overlooking the town is the castle rebuilt by Louis II., duke of Bourbon, and Henry IV. during the religious wars; it serves as a barracks. Montluc is the site of a military tribunal of first instance and of commerce, a board of trade arbitration, a chamber of commerce and a lycée. The town, which formed part of the duchy of Bourbon, was taken by the English in 1275, and by Philip Augustus in 1281; the English were beaten under its walls in the 14th century.

MONTMORENCY, the name of one of the oldest and most distinguished families in France, derived from Montmorency, now in the department of Seine-et-Oise, in the immediate neighbourhood of Enghien and St Denis, and about 9 m. N.N.W. of Paris. The family, since its first appearance in history in the person of Bouchard I., sire de Montmorency in the 10th century, has furnished six constables and twelve marshals of France, several admirals and cardinals, numerous grand officers of the Crown and grand masters of various knightly orders, and was declared by Henry IV. to be, after that of the Bourbons, the first house in Europe. Mathieu I., sire de Montmorency, received in 1358 the post of constable, and died in 1362. His first wife was Aline, the natural daughter of Henry I. of England, and by her bore Louis V., and afterwards married Louis VI. and mother of Louis VII., and according to Duchesne, he shared the regency of France with Suger, during the absence of the latter king on the second crusade. Mathieu II. had an important share in the victory of Bouvines (1214), and was made constable in 1218. During the reign of Louis VIII. he distinguished himself chiefly in the south of France (Niort, La Rochelle, Bordeaux). On the accession of Louis IX. he was one of the chief supports of the queen-regent Blanche of Castile, and was successful in reducing all the vassals to obedience. He died in 1230. His younger son, Guy, in right of his mother, became head of the house of Montmorency-Laval. Anne de Montmorency (1505-1567), so named, it is said, after his godmother Anne of Brittany, was the first to attain the ducal title (1551). His eldest son, François de Montmorency (1530-1579), was married to Diana, natural daughter of Henry II.; another son, Henri I. de Montmorency (1534-1614), who became duc de Montmorency on his brother's death in 1599, had been governor of Languedoc since 1563. As a leader of the party called the Politiques he took a prominent part in the French wars of religion. In 1593 he was made constable, but Henry IV. showed some anxiety to keep him away from Languedoc, which he ruled like a sovereign prince. Henry II. (1595-1632), the second son of Henry I., succeeded to the title in 1614, having previously been made grand admiral. He also was governor of Languedoc. In 1625 he defeated the French Protestant fleet under Soubise, and seized the islands of Ré and Oléron, but the jealousy of Richelieu deprived him of the means of following up these advantages. In 1629-1630 he was allowed to command against the duke of Rohan in Languedoc; in 1630 he defeated the Piedmontese, and captured Prince Doria, at Avigliana, and took Saluzzo. In the same year he was created marshal. In 1632 he joined the party of Gaston, duke of Orleans, and placed himself at the head of a force, which was defeated by Marshal Schomberg at Castelnaudary (1632); subdued, he fell into the enemy's hands, and, abandoned by Gaston, was executed as a traitor at Toulouse on the 30th of October. The title passed to his son Charles-Marguerite, duchesse de Lessé, sister of Condé.

From the barons of Fosseux, a branch of the Montmorency family established in Brabant in the 15th century, sprang the seigneurs de Boutteville, among whom was the duellist François de Montmorency-Boutteville, who was beheaded in 1627. His son, François Henri, marshal of France, became duke of Piney-Luxemburg by his marriage with Madeleine Charlotte Bonne Thérèse de Clermont, daughter of Marguerite Charlotte de Luxembourg, duchesse de Piney. Charles François Frédéric, the son of the marshal, was created duke of Beaufort in 1658 and duke of Montmorency in 1689. In 1767 the title of duke of Beaufort-Montmorency passed by marriage to another branch of the Montmorency-Fosseaux. This branch becoming extinct in 1862, the title was taken by the duc de Valencey, who belonged to the Talleyrand-Périgord family and married one of the branches of this branch (1864). There were many other branches of the Montmorency family, but the sons of some of the seigneurs of Laval (p.), a cadet branch of which received the title of duc de Laval and settled on the estate of Magnac in 1758. It is to this branch that Mathieu, duc de Montmorency (1767-1826), diplomatist and writer, and tutor of Charles X.'s grandson, Henri, duc de Bordeaux, belonged.

MONTMORENCY, ANNE, DUC DE (1483-1567), constable of France, was born at Chantilly, and was brought up with the future King Francis I., whom he followed into Italy in 1515, distinguishing himself especially at Marignano. In 1516 he became governor of Novara; in 1520 he was present at the Field of Cloth of Gold, and afterwards had charge of important negotiations in England. Successful in the defence of Mélunès (1521), and as commander of the Swiss troops in the Italian campaign of the same year, he was made marshal of France in 1522, accompanied Francis I. into Italy in 1524, and was taken prisoner at Pavia in 1525. Released soon afterwards, he was one of the negotiators of the treaty of Madrid, and in 1530 reconquered Aix-en-Provence for the king of France. On the renewal of the war by Charles V.'s invasion of France in 1535, he carried the emperor to raise the siege of Marseilles; he afterwards accompanied the king of France into Picardy, and on the termination of the Netherlands campaign marched to the relief of Turin. In 1538, on the ratification of the ten years' truce, he was rewarded with the office of constable, but in 1541 he fell into disgrace, and did not return to public life until the accession of Henry II. in 1547. In 1548 he repressed the insurrections in the south-west, particularly at Bordeaux, with great severity.
and in 1549–50 conducted the war in the Boulonnais, negotiating the treaty for the surrender of Boulogne on the 24th of March 1550. In 1551 his barony was erected into a duchy. Subsequently his son, Mathieu de Montmorency-Laval, was governor in connexion with the seizure of Mâcon, Toul and Verdun by the French king. His attempt to relieve St Quentin resulted in his defeat and capture (Aug. 10, 1557), and he did not regain his liberty until the peace of Cateau-Cambrésis in 1559. Supplanted in the interval by the Guises, he was treated with coldness by the new king, Francis II., and compelled to give up his mastership of the royal household—his son, however, being appointed marshal by way of indemnity. On the accession of Charles IX., in 1560 he resumed his offices and dignities, and, uniting with his former enemies, the Guises, played an important part in the Huguenot war of 1562. Though the arms of his party were victorious at Dreux, he himself fell into the hands of the enemy, and was not liberated until the treaty of Amboise (March 19, 1563). In 1567 he again triumphed at St Denis, but received the death-blow of which he died at Paris, on the 15th of March, 1567.

See P. Descle, Anne de Montmorency (Paris, 1885), and Anne, duc de Montmorency (Paris, 1889).

MONTMORENCY, MATHIEU JEAN FÉLICITÉ DE MONTMORENCY-LAVAL, Duc de (1766–1826), French politician, was born in Paris on the 10th of July 1766. He served with his father, the vicomte de Laval, in America, and returned to France imbued with democratic opinions. Mathieu de Montmorency was governor of Compiègne when he was returned as deputy to the states-general in 1789, where he joined the Third Estate and sat on the left of the Assembly. He moved the abolition of armorial bearings on the 19th of June 1790. The dissolution of the Constituent Assembly in September 1791 set him free to join Lückner’s army on the frontier early in the next year. After the revolution of the 10th of August he abandoned his revolutionary principles; and he took no part in politics under the empire. At the Restoration he was promoted maréchal de camp, and accompanied Louis XVIII. to Ghent during the Hundred Days. At the second restoration he was made a peer of France, and two years later received the title of viscount. He adopted strong reactionary and ultramontane views, and became minister of foreign affairs under Villèle in 1821. He recommended armed intervention in Spain at the Congress of Verona in October 1822, but he resigned in December, being compensated by the title of duke and the cross of the Legion of Honour in the next year. He was elected to the French Academy in 1825, though he appears to have had small qualifications for the honour, and in the next year became tutor to the six-year-old Henri (afterwards King of Bordeau [afterwards known as the comte de Chambord]). He died two months after receiving this last appointment, on the 24th of March 1826.

See Vétillard, Notice sur la vie de M. le duc Mathieu de Montmorency (Le Mans, 1826), and, for his curious relations with Mme de Staël, P. Gautier, Mathieu de Montmorency et Mme de Staël, d’après les lettres inédites de M. de Montmorency à Mme Necker de Saussure (1908).

MONTMORENCY, a town of northern France in the department of Seine-et-Oise, 21⁄2 m. from the right bank of the Seine and 11 m. N. of Paris by rail. Pop. (1906), 5723. In the middle ages it was the seat of the family of Montmorency. There is a church built for the most part in the 16th century by Anne de Montmorency. The town is a well-known resort of Parisians. To the north-east lies the fine forest of Montmorency. Bleaching and dyeing and the manufacture of lime plaster, bricks and tiles are carried on. About a mile south-west lies Enghien-les-Bains (pop. 4925), the waters of which are used in cases of cataract and skin disease.

MONTMORILLON, a town of western France, capital of an arrondissement in the department of Vienne, on the Garateme, 34 m. E.S.E. of Poitiers by rail. Pop. (1906), 3924. The ecclesiastical seminary occupies a building of the 12th century, formerly an Augustinian convent. The convent church is Romanesque in style and there is a curious two-storied chapel of octagonal form, of the same period. The church of Notre-Dame is a combination of Romanesque and Gothic, dating from the 12th and 13th centuries.

MONTMORIN, HÉREM, ARMAND MARC, COMTE DE (1745–1790), French statesman, belonged to a cadet branch of a noble family of Auvergne. He was gentleman-in-waiting to Louis XVI. when dauphin, and was subsequently appointed ambassador at Madrid. From Madrid he was suddenly summoned to the government of Brittany, and in 1787 was appointed by the king to succeed Vergennes in the ministry of foreign affairs. Montmorin was a devoted admirer of Necker, whose influence at the court he was mainly instrumental in maintaining. He retired when Necker was dismissed on the 12th of July 1789, but on Necker’s recall after the taking of the Bastille again resumed his office, which he continued to hold till October 1791. Mirabeau (q.v.) had approached him so early as December 1788, with a plan for the policy to be pursued by the court towards the new states general; but Montmorin, offended by Mirabeau’s attacks on Necker and by his Histoire secrète de la cour de Berlin, refused to see him. With the progress of the Revolution, however, this attitude was changed. The comte de la Marck was exerting himself to bring Mirabeau into touch with the court (see MIRABEAU), and for this purpose it was important to secure the assistance of Montmorin. The convenience of an understanding between the two men was obvious; and they were soon on the closest terms. While Mirabeau continued minister of finance, Montmorin came so in fact. Montmorin did not dare to come to a decision without consulting his masterful friend, but on the other hand neither Mirabeau nor La Marck were under any illusions as to the broken character of the reed on which they had perfec to lead. Mirabeau complained bitterly that Montmorin was “slack” (“flasque”) and a “poltroon” (“gâsache”). On the other hand, La Marck thought that Montmorin’s feebleness was occasionally useful in restraining Mirabeau’s impetuosity. The death of Mirabeau in April 1791 was a severe blow to Montmorin, the difficulty of whose position was enormously increased after the flight of the royal family to Varennes, to which he was not privy. He was forced to resign office, but still continued to advise Louis, and was one of the inner circle of the king’s friends, called by the revolutionists “the Austrian Committee.” In June 1792 his papers were seized at the foreign office, without anything incriminating being discovered; in July he was denounced, and after the 10th of August was proscribed. He took refuge in the house of a washerwoman, but was discovered, haled before the Legislative Assembly, and imprisoned in the Abbaye, where he perished in the September massacres. His relative, Louis Victor Henri, marquis de Montmorency de Saint-Hérem, head of the elder branch, also perished in the massacre.

MONTORO, a town of southern Spain, in the province of Cordova, 27 m. E. by N. of the city of Cordova, on the Madrid-Cordova railway. Pop. (1900), 14,581. Montoro was the Epîtres of the Romans, and became an important Moorish fortress in the middle ages, but it has been largely modernized. It stands on a rocky peninsula on the south bank of the Guadalquivir, here crossed by a fine bridge of four arches dating from the 16th century. Oil is largely manufactured, and there is considerable trade in timber, agricultural produce and livestock.

MONTPELIER, a city, the capital of Vermont, U.S.A., and the county-seat of Washington county, on the Winooski river, 40 m. (by rail) E.S.E. of Burlington. Pop. (1900), 5266 (52% foreign-born); (1910), 7856. Montpelier is served by the Central Vermont and New Hampshire & Montpelier & Wells River railways. Barre granite is mined extensively in the vicinity, and the city manufactures marble and granite products, flour, lumber, saddlery
Montpellier—Montpensier

hardware and wood-working machinery. The principal building is the state house, crowned by a statute of Agriculture by Larkin G. Mead. The state house was first occupied in 1836. It was almost completely destroyed by fire in 1857, and was subsequently rebuilt and enlarged. Other prominent features of the city are the United States government building, the county court house, the Montpellier seminary and the Wood art gallery, a collection consisting principally of paintings by Thomas Waterman Wood (1823-1903), a native of Montpellier. The town of Montpellier, named from the city in France, was granted to a company of sixty proprietors in 1780. The first permanent settlement was made in 1785; and the town was  organized in 1791 under a charter of 1781, replaced by another in 1804. In 1805 it was selected as the capital of the state, and in 1808 the legislature met here for the first time. At first the town was a part of Orange county, but in 1810 Washington county was created, and in 1811 Montpellier became the seat of government of the new county. In 1849 East Montpellier was set apart as a separate township, and in 1894 the town of Montpelier was chartered as a city.

Montpellier, a town of southern France, capital of the department of Hérault, about 7 m. from the Mediterranean, and 31 m. S.W. of Nîmes on the Paris-Lyon railway between that town and Cetîe. Pop. (1906), 65,983. Montpellier, the seat of a university and the principal place of lower Languedoc, is situated in a fruitful plain less than a mile from the right bank of the small river Lez. Composed for the most part of narrow winding streets, the town has at the same time several spacious thoroughfares and some fine squares and promenades, notably the much-frequented Place de la Comédie, the Esplanade and the Peyrou. The last terminates in a terrace commanding a magnificent view of the coasts of the Mediterranean, and of the Pyrenees and Alps. On the terrace is situated the reservoir of the town, the water being brought from a distance of about 8 m. by an aqueduct. In the centre of the square is an equestrian statue of Louis XIV., while opposite the entrance is the Porte de Peyrou, a triumphal arch erected at the end of the 17th century to commemorate the achievements of Louis XIV. The Boulevard Henri IV. to the north leads past the botanical garden, founded in 1793 and thus the oldest in France, the medical college, and the cathedral; to the east the Rue Nationale leads to the palace of justice, the prefecture, and the citadel. The cathedral (14th century), which until 1536 was the church of a Benedictine monastery, suffered severely during the religious wars, and about the middle of the 19th century the choir and one of the four towers at the angles of the nave were rebuilt in the style of the 13th century. The monastery, after being converted into the bishop's palace, has since 1795 been occupied by the famous medical school. A gallery devoted to the portraits of professors since 1239 contains one of Rabelais. Close to the medical school is the Tour des Pins, the chief relic of the medieval fortifications. The museum (Musée Fabre) contains rich collections of Italian, Flemish, Dutch and modern French paintings and of French sculptures. Its most valuable is the collection given to it by the painter F. X. P. Fabre (1766-1837), born at Montpeller. The principal public buildings are the palace of justice—a modern structure, the theatre and the prefecture, also modern. Montpellier possesses old houses of the 15th and 16th centuries. The Lez is canalized so as to connect Montpellier with the canal du Midi and with the sea at Palavas. The town has a considerable trade in wine, brandy, fruit and silk. The principal industrial establishment is a manufactory for candles and soap. There are also tanneries, distilleries and manufactories of cotton and woollen goods, chemicals, glass, china and hardware. Montpellier university comprises faculties of medicine, law, science and letters, and a higher school of pharmacy. Montpellier is also the seat of a bishop and a prefect, of courts of appeal and assizes, tribunals of first instance and of commerce, a chamber of commerce, a board of trade and arbitration, and headquarters of the XVI. army corps.

Montpellier first rose into importance after the destruction of Maguelonne by Charles Martel in 737. In the 10th century it consisted of two portions, Montpellier and Montpellier, held by the bishops of Maguelonne by the family of Guilhem. The Guilhems were succeeded, through marriage, by the house of Aragon, a member of which in 1349 sold his rights to Philip of Valois, Montpellier et having already in 1292 been ceded to the Crown by the bishops. In 1441 Montpellier acquired a charter afterwards materially extended, and the same century saw the rise of its school of medicine. Several of the ablest teachers of that school were members of an important Jewish colony established in the town. It had a school of law in 1160, and a university was founded by Pope Nicholas IV. towards the close of the 13th century. Louis IX. granted to Montpellier the right of free trade with the whole of the kingdom, a privilege which greatly increased its prosperity. The importance of the town was enhanced when the bishopric of Maguelonne was transferred thither in 1536. During the wars of religion the town was a stronghold of the Protestants, who captured it in 1567. It strenuously supported the duke of Rohan in his revolts and in 1622 only succumbed to Louis XIII. after a siege of eight months. In 1628 the duke was defeated there and the walls of the town razed, the royal citadel built in 1624 being, however, spared. Louis XIII. made Montpellier the seat of one of the généralités of Languedoc, and the states of that province met there during the 17th and 18th centuries.

See A. C. Germain, Histoire du comte de Montpellier antérieure-ment à l'ouverture du port de Côte (2 vols., Montpellier, 1861), and Histoire de la commune de Montpellier (3 vols., Montpellier, 1851); Aigrefeuille, Histoire de la ville de Montpellier (4 vols., Montpellier, 1875-1882).

Montpensier, Counts and Dukes of. The French lordship of Montpensier (department of Puy-de-Dôme), which became a countship in the 14th century, was sold in 1358 by Bernard and Robert de Ventadour to John, duke of Berry, whose daughter Marie brought the countship to her husband, John I., duke of Bourbon, in 1400. The countship was subsequently held by Louis de Bourbon, younger son of Duke John, and by his descendants up to Charles de Bourbon-Montpensier, the famous constable, who became duke of Bourbon by his marriage with his cousin, Suzanne de Bourbon, in 1505. Confiscated by King Francis I., the countship was restored in 1538 to Louise de Bourbon, sister of the constable, and widow of the prince de La Roche-sur-Yon, and to her son Louis (1513-1582), who was erected into a duchy in the peerage of France (duché-pairie) in 1539. Marie, daughter and heiress of Henri de Bourbon, duke of Montpensier, brought the duchy to her husband Gaston, duke of Orleans, brother of Louis XIII., whom she married in 1626, and their daughter and heiress (see below), known as "La Grande Mademoiselle," was duchess of Montpensier. The title subsequently remained in the Orleans family, and was borne in particular by Antoine Philippe (1775-1807), son of Philippe "Egalité," and Antoine Marie Philippe Louis (1824-1890), son of King Louis Philippe and father-in-law of King Alphonso XII. of Spain.

Montpensier, Anne Marie Louise d'Orléans, Duchesse de (1627-1693), French memoir-writer, was born at the Louvre on the 29th of May 1627. Her father was Gaston of Orleans, "Monsieur," the brother of Louis XIII. Her mother was Marie de Bourbon, heiress of the Montpensier family. Being thus of the blood-royal of France on both sides, and heiress to immense property, she appeared to be very early destined to a splendid marriage. It was perhaps the greatest misfortune of her life that "la grande mademoiselle" was encouraged to look forward to the throne of France as the result of a marriage with Louis XIV., who was, however, eleven years her junior. Illuck, or her own willfulness, frustrated numerous plans for marrying her to persons of exalted station, including even Charles II. of England, then prince of Wales. She was just of age when the Fronde broke out, and, attributing as she did her disappointments to Masani, she sympathized with it not a little. In the new or second Fronde she not only took nominal command of one of the
armies on the princess’ side, but she literally and in her own person took Orleans by escalade. However, she had to retreat to Paris, where she practically commanded the Bastille and the adjoining part of the walls. On the 2nd of July 1652, the day of the battle of the Faubourg Saint Antoine, between the Frondeurs under Condé and the royal troops under Turenne, Mademoiselle saved Condé and his beaten troops by giving orders for the gates under her control to be opened and for the cannon of the Bastille to fire on the royalists. In the heat of the émeute which followed she installed herself in the Hôtel de Ville, and played the part of mediatrix between the opposed parties. Her political importance lasted exactly six months, and did her little good, for it created a lifelong prejudice against her in the mind of her cousin, Louis XIV. She was for some years in disgrace, and resided on her estates. It was not till 1657 that she reappeared at court, but, though projects for marrying her were once more set on foot, she was now past her first youth. She was nearly forty, and had already corresponded seriously with Mme de Mottetville on the project of establishing a ladies’ society “sans mariage et sans amour,” when a young Gascon gentleman named Puyluguin, afterwards celebrated as M. de Lauzun (q.e.), attracted her attention. It was some years before the affair came to a crisis, but at last, in 1670, Mademoiselle solemnly demanded the king’s permission to marry Lauzun. Louis, who liked Lauzun, and who had been educated by Mazarin in the idea that Mademoiselle ought not to be allowed to carry her vast estates and royal blood to anyone who was himself of the blood-royal, or even to any foreign prince, gave his consent, but it was not immediately acted on, as the other members of the royal family prevailed with Louis to rescind his permission. Not long afterwards Lauzun, for another cause, was imprisoned in Pignerol, and it was years before Mademoiselle was able to buy his release from the king by settling no small portion of her estates on Louis’s bastards. The elderly lovers (for in 1651, when Lauzun was released, he was nearly fifty, and Mademoiselle was thirty-nine) married, and Lauzun was created the Duke of Lauzun. However, the marriage was not a happy one. Mademoiselle tyrannized over his wife, and it is said that on one occasion he addressed her thus, “Louise d’Orléans, tire-moi mes bottes!” and she at once and finally separated from him. She lived for some years afterwards, gave herself to religious duties, and finished her Mémoires, which extend to within seven years of her death (April 9, 1693), and which she had begun when she was in disgrace thirty years earlier. These Mémoires (Amsterdam, 1729) are of very considerable merit and interest, though, or perhaps because, they are extremely egotistical and often extremely desultory. They are to be found in the great collection of Michaud and Pouloujat, and have been frequently edited apart. Her Eighte Beulades has been edited by E. Rodocanachi as Un Ouvrage de piètié inconnu (1968).

See the series of studies on La Grande Mademoiselle, by “Arvède Barthe” (1902) (G.S.A.)

MONTREAL, a city of the Dominion of Canada, its leading seat of commerce and principal port of entry, as well as the centre of many of its important industries. It is situated on the southeast of the island of Montreal, at the confluence of the Ottawa and St Lawrence rivers, in the county of Hochelaga and province of Quebec. The observatory in the grounds of McGill University, in the city, has been determined to be in 45° 30’ 17” N. lat., and 73° 34’ 40-05” W. long. The city holds a fine position at the head of ocean navigation, nearly a thousand miles inland, and at the foot of the great system of rivers, lakes and canals upon which the commerce of the interior is carried to the Atlantic seaboard. The ship channel below Montreal permits the passage of ocean vessels drawing 30 ft. at low water. The deepening of the channel, largely due to the initiative of Montreal merchants, was begun in 1844 by the government of Canada. The work was transferred to the Harbour Commissioners of Montreal in 1850. The depth of the channel was then 11 ft. Fifteen years later it had gradually been increased to 20 ft.; and in 1888, when the work was taken over by the Dominion government, the depth was 27 ft. 6 in. The Lachine canal, with the chain of artificial waterways that succeeded it, opened the way for the shipping of the Great Lakes. The first sod in the digging of the Lachine canal was turned in July 1821 by John Richardson of Montreal. The same public-spirited merchant presided in April of the following year at the preliminary meeting which led to the formation of the committee of trade, itself the forerunner of Montreal’s indispensable board of trade. Even before the close of the French régime in Canada efforts had been made to cut a canal across the island of Montreal, and M.de Catalogne succeeded in building a waterway practicable for the canoes of the fur-traders. The more ambitious canal commenced in 1821 was completed four years later, at a cost of $440,000. Before its completion, however, the increasing draught of inland shipping made it practically useless, and in 1843 work was begun on an enlargement. Since then the canal has been repeatedly deepened, to keep pace with the requirements of lake shipping, until to-day a 14-ft. channel is available.

In the meantime the rival method of rail transportation was taking shape, and in 1856 the first Canadian railway was opened, between Laprairie, opposite Montreal and St John’s, in the eastern townships. In 1848 a second railway, from Longueuil to St Hyacinthe, was opened; both these projects owing their existence to the enterprise of Montreal citizens. The broad St Lawrence, however, still lay between the city and the outside world. In 1854 work was commenced upon the famous Victoria tubular bridge, designed by Robert Stephenson and A. M. Ross. The bridge was opened by King Edward VII., then prince of Wales, in 1860. In 1862 it was replaced by the Victoria Jubilee bridge, built on the piers of the old bridge. At the foot of Lake St Louis, some distance above the Victoria Jubilee bridge, the Canadian Pacific railway crosses the river on a graceful cantilever bridge with two central spans each 208 ft. long. Montreal is on the Canadian Pacific, Grand Trunk, Intercolonial, Canadian Northern, New York Central, Rutland, Central Vermont and Delaware & Hudson railways. During the season of navigation there is a regular steamer service between Montreal and the principal ports of the Lakes and St Lawrence. By rail communication with Liverpool, London, Glasgow, Bristol and other British and European ports, as well as the principal ports on the river and gulf of St Lawrence and the Great Lakes. A system of electric railways covers every section of the city and affords easy communication with the suburbs and neighbouring towns.

Built originally along the water-front, Montreal has in the course of years swept back over a series of terraces—former levels of the river or of a more ancient sea—to the foot of Mount Royal. Held there, it has been forced around the mountain on either side. Mount Royal, from which the city derives its name and so much of its natural beauty, is a mass of trap-rock thrown up through the surrounding limestone strata to a height of 753 ft. above the level of the sea. Under the direction of Frederick Law Olmsted, it was converted into a magnificent park. Between mountain and river the Lachine canal winds through the city. In the middle of the river lies the beautifully wooded St Helen’s Island, rising to a height of 170 ft. above the water, and itself commanding an excellent view of the city. The island, named after Helen Boulé, wife of Champlain, belonged at one time to the barons of Longueuil. The British government purchased it for military purposes, and it still contains a battery of guns and barracks, the latter tenantless, since the island has been loaned to the city for use as a public park.

The city is substantially built, grey limestone, quarried from the mountain, predominating in the public and many of the private edifices. On the south of the Place d’Armes, a small enclosure covering the site of an ancient burying-ground, stands the parish church of Notre Dame, whose Gothic outlines form one of the striking features of the city. Designed by James O’Donnell, the church was built in 1824 to take the place of an earlier structure dating back to 1672. The existing church is 255 ft. long and 134 ft. wide, and accommodates 10,000 worshippers. Its twin towers (227 ft.) contain ten bells, one of which, known as “Le Gros Bourdon,” weighs 24,750 lb, the largest in America. Two others weigh respectively 6041 and 1635 lb. Beside the church stands the historic seminary of St Sulpice, one of the
few remaining relics of the days of French rule. This ancient
building is now used for the offices of the Order of Sulpicians,
founder by the Abbé Olier in the early half of the 17th century.
This zealous enthusiast had sent out Paul de Chomedey, sieur de
Maisonneuve, in 1641 to establish the missionary enterprise
which afterwards developed into the city of Montreal, and six
years later the Abbé de Quelus, with three devoted companions,
landed at Ville-Marie de Montreal and laid the foundations
of the future powerful Order of Sulpicians. The seigneurie
of Montreal, acquired by Olier in 1640, is still held by the
Sulpicians, and as they have retained large blocks of land in the
heart of the city as well as elsewhere on the island, these “Gentlemen
of the Seminary,” as they were locally called, rank among the
wealthiest societies in America. The head offices of the Bank
of Montreal face Notre Dame church, on the north of the Place
d'Armes, and several other of the leading banking institutions
of the city have their quarters in the immediate neighbourhood.
In the Place d'Armes itself stands a striking figure in bronze
erected to the memory of the founder of Montreal, Maisonneuve.
At the base are a series of bas-reliefs setting forth historical
incidents connected with the early history of the town. The
monument is the work of a Canadian sculptor, Louis Philippe
Hebert. The figure of Gaspard de la Vérendrye, its bronze
top stands upon Dominion Square. It is an almost exact repro-
cuction, reduced to one-half the scale, of St. Peter's at Rome. The
building, projected by the late Archbishop Bourget to replace the
old church on St Denis street destroyed in the great fire of
1852, was begun in 1868. On the west of the square stand the
Windsor Street station of the Canadian Pacific railway;
St George's (Anglican) church, which possesses a fine chime of
bells; and the Windsor Hotel. A statue of Sir John Macdonald
occupies the centre of the square. Close to the historic Bon-
secours Market stands the church of Notre Dame de Bonsecours,
founded by Sister Marguerite Bourgeois in 1673 as a sanctuary
for a miraculous statue of the Virgin. The original church was
burned in 1754, and the present building, erected in 1771, an
example of Norman architecture transplanted to the New World,
narrowly escaped destruction to make room for a railway
station. Curiously enough, it remained for a number of English
Protestants to secure the preservation of this relic of the French
period. Jacques Cartier Square, adjoining Bonsecours Market,
is notable for its column and statue of Nelson, erected in 1808.
As the Roman Catholic of England owes its existence to the
energy and enthusiasm of Archbishop Bourget, so Christ Church
cathedral must always be associated with the name of the first
residence Anglican bishop of Montreal, Dr Fulford. The church
is a fine example of the Early English style of architecture.
Beside it stands a memorial of Bishop Fulford, modelled after
the famous Martyr's Memorial at Oxford.

The mixture of races and creeds, which is so striking a charac-
teristic of Montreal life, has not only endowed the city with many
beautiful churches, but also with varieties of philanthropic
institutions. Each of the several national societies—St George's,
St Andrew's, St Patrick's, and that of the French-Canadian
patron saint, St Jean Baptiste, to mention no others—looks after
the welfare of its own adherents. Of the several hospitals, the
most venerable is the Hôtel Dieu, founded in 1644 by Mme de
Bouillon, a French lady of high rank. The original building,
in the early days of Ville Marie, stood without the fort, and was
fortified to withstand the attacks of the Iroquois. The site
is now covered by a block of warehouses on St Paul Street.
The present building, completed in 1838, contains both a hospital
and a nursery. The Order of the Grand Monseigneur, a
Canadian lady, Mme d'Oyville, in 1737, cares for hundreds
of foundlings and aged and infirm people in the great hospital
in Guy Street. The Montreal General hospital was founded in
1819 by public subscriptions, and the Royal Victoria hospital
is a monument to the generosity of Lord Strathcona and Lord
Mount-Stephen. Besides these should be mentioned the
Notre Dame, the Western and the Children's Memorial hospitals.
Separate hospitals for contagious diseases are maintained both
by the Roman Catholics and Protestants.

Montreal provides for the education of its young people through
two distinct systems of public schools, one for Roman Catholics,
the other for Protestants, each governed by a board of commis-
sioners. The schools are maintained by an annual tax based
upon the assessment, two-fifths of 1% being levied upon the
Protestant section of the community for the support of the
Protestant schools, and one-quarter of 1% upon the Catholics
for their schools. Unlike the neighbouring provinces of Ontario,
Quebec makes no provision for a state university. But James
McGill (1744-1815) left property, valued at the time of his death
at $50,000, for the foundation of a university, one college of
which was to bear his name. A royal charter conferring univer-
sity powers was obtained in 1821. During early years slow
progress was made, but with the appointment of Sir William
Dawson as principal, in 1855, the institution entered on a career
of prosperity. It now embraces five faculties: arts, applied
science, law, medicine, agriculture, and comprises the following:
McGill College, Montreal, the original foundation; the Royal
Victoria College for Women, Montreal, built and endowed by
Lord Strathcona; four affiliated theological colleges in Montreal;
the Macdonald College, erected and endowed by Sir William
C. Macdonald, at Ste Anne de Bellevue, 20 m. from the city;
the University of British Columbia, Vancouver, B. C.; and three
affiliated women's institutions: Mount Royal College, Stanstead,
P.Q.; Victoria College, Victoria, B.C.; Alberta College, Edmonton. The finely-equipped Macdonald scientific
laboratories, with the Redpath Museum and University Library
(114,000 vols. in 1907), form part of a noble group of buildings
on the campus in Montreal. Disastrous fires in April 1907
wiped out two buildings and destroyed the splendid medical
museum, but the plans for rebuilding provided for further
extension and improvement. Previous to the fires the property
of the university in buildings in Montreal, including equipment
and endowment, was valued at $6,000,000.

The French university of Laval, the chief seat of which is in
the city of Quebec, also maintains a branch at Montreal, established
in 1877. It embraces the faculties of arts, law, medicine and
theology, the latter conducted through the Seminary of St
Sulpice. The college library has been enriched by a rare collec-
tion of Canadian books and manuscripts, bequeathed by Judge
Louis François Georges Baby (1834-1906), of Montreal. The
medical school, which now occupies a portion of the university
building, formerly held its sessions in the historic Chateau de
Ramezay, built by the Cherokees and enlarged by Governor
Montreal, in 1704, and occupied after the conquest by the British
of Canada, until the burning of Lord Elgin and the
Parliament Buildings in 1849 brought about the
removal of the seat of government from Montreal. The Chateau
de Ramezay is now the fitting home of a public collection
of historic relics. Of other educational institutions in the city the
most important is St Mary's College, founded in 1848 by the
Jesuits, and removed to the present building in 1855. The
archives boast a notable collection of early Canadian manu-
scripts, upon which Francis Parkman drew in preparing his
histories of New France.

Montreal's position as the chief doorway of the outgoing and
incoming trade of the Dominion is largely due to the foresight
of her great merchants. With the gradual opening up of means
of communication by land and water, and the development of
her facilities for handling the imports and exports of the country,
the city has increased rapidly in importance, until day after
year, the imports of the Dominion come through Montreal,
and nearly 30% of the exports. In shipments of grain Montreal
has eclipsed all her rivals on the continent except
New York and New Orleans, and the building of the Georgian Bay
canal will, by materially shortening the distance between the
western grainfields and European markets, give her a very
considerable advantage over both these ports. In dairy produce
she is already the chief export centre of the continent. Montreal
is also the financial centre of Canada, and in it are to be found
the head offices of more than 25 important banks, of the leading
insurance companies, and of the two greatest railways of the country.
MONTRESOR—

Montreal is governed by a mayor and 36 aldermen, elected every two years. The city returns 5 members to the Dominion House of Commons and 6 to the Provincial Legislature of Quebec.

The population of Montreal, according to the census of 1901, was 266,826. With the suburbs, it was estimated in 1907 at over 405,000, about three-fifths French.

The history of the town is steeped in romance. From that first remarkable scene, so graphically described by Francis Parkman, when, on the 18th of May 1642, Maisonneuve and his little band of religious enthusiasts landed upon the spot where the Montreal Custom House now stands, and planted, in the words of the saintly Dumont, a grain of mustard seed destined to overshadow the land, the history of the town was to be intimately associated with missionary enterprise and such missionary heroism as the world has rarely seen. Montreal began as a religious colony, but its very situation, on the outer confines of civilization and at the door of the Iroquois country, forced it to become a military settlement, a fortified town with a military garrison. Similarly its position, even then an ideal one from a commercial point of view, made it the dominating centre of the fur-trade. For a hundred years after its foundation these three influences held sway, more or less mutually antagonistic, the streets of Montreal presenting an animated picture of sombre priests and jovial soldiers, savage hunters in their native finery and more than half-savage fur traders. Within another hundred years, although both priests and soldiers were still to be seen on their streets, they had become but atoms in a larger and more varied population. The fur trader of New France, merged after the conquest in the fur trader of the North West Company—which had its origins in Montreal—remained for a time the picturesque survival of earlier and more romantic days. Finally, he too disappeared in the multiform and strenuous life of the modern city.

MONTRESOR, CLAUDE DE BOURDEILLE, COMTE DE (c. 1600-1663), French intriguer and memoir-writer, was the grand-nephew of Pierre de Brantôme. He was the second favourite of Gaston, duke of Orleans, the weak brother of Louis XIII., succeeding Antoine de La De, duc de Puylaurens, in this position in 1635. He planned the assassination of Cardinal Richelieu at the camp of Amiens in 1636, a plan which failed through the cowardice of Orleans. Montréal was obliged to spend the next six years on his estate, but in 1642 he entered into the plot of Cinco Mars against Richelieu. On its failure he escaped to England, but his estates were confiscated. Returning from Richelieu's death, he entered into the intrigues of the period just preceding the Fronde, and was imprisoned in the Bastille, then in Vincennes, having risked his safety by coming back from exile in Holland to aid the duchess of Chevreuse. Mazarin attempted to win him over in vain, but in 1653 he made his submission to the victorious minister, and from that time on played no part in public life. He had three children by Mlle de Guise, with whom he had a lasting liaison.

His Mémoires have preserved his name from the oblivion other- wise awaiting such intriguers; they are written with naive frankness and are extremely interesting. They are printed by A. Petitot and A. Duby in Collection des mémoires relatifs à l'histoire de France (Paris, 1876).

MONTREUIL, GERBER DE (fl. 13th century), French troubadour, author of the Roman de la violette. He dedicated his poem (c. 1221) to the Countess Marie of Ponthieu, wife of Simon, count of Dammartin and a niece of Philip Augustus. The count Gerard de Nevers of the story stakes his domains on the fidelity of his wife Euriart. Lisiard by calumniating Euriart wins the wager, but in the end the traitor is exposed, and, after many adventures, Euriart is reinstated. Another version of the story is given in the Roman de la Comte de Poitiers and in the tale in the Decameron (ii. 9) on which Shakespeare founded Cymbeline. Lyric is inserted in the narrative of the Roman de la violette, as they had been in the Ceste de la rose (1200), known also as Guillaume de Dale. A prose version, dating from the early 15th century, provided Wilhelmine de Chézy with the material for her libretto of Weber's opera, EURYANTHE (1823).

See Hist. lit. de la France, xxii. 780, xxvii. 760, xxviii. 826; Le roman de Poitiers (ed. F. Michiel, 1831); Le Roman de la violette (ed. F. Michiel, 1834); Le Ceste de la rose (ed. Servois, 1853); F. Kraus, Uber Gerber de Montreuil (Erlangen, 1897); Rudolf Ohle, Shakespeare's Cymbeline und seine romantischen Vorläufer (Berlin, 1890).

MONTREUIL-SOUS-BOIS, a town of northern France, capital of an arrondissement in the department of Pas-de-Calais, 24 m. S. by E. of Boulogne by rail. Pop. (1906), 35,831. Montreuil is especially noted for its extensive peach orchards. The manufactures include paint, oils and varnish, glass and chemical products.

MONTREUIL-SUR-MER, a town of northern France, capital of the department of Pas-de-Calais, 12 m. by S. of Boulogne. Pop. (1906) 26,824.

MONTREUX, the general name applied to the villages situated along the shore at the east of the Lake of Geneva in Switzerland, from Clares to Veytaux: sometimes the name is strictly applied to Vernex only. These villages form part of 3 communes, those of Le Châtelard (including Clares and Vernex) and of Les Planches (including Territet), while a bit (not Chillon) of that of Veytaux is alone included. The total population of this “agglomeration” was 14,144 in 1900, mostly French-speaking, while there were 9730 Protestants to 3431 Romanists and 55 Jews.

There are railway stations at Clares (15 m. south-east of Lausanne), at Vernex (4 m. on), and Territet (1 m. on, or 2 m. from Veytaux, which is 14 m. north of Villeneuve), as well as an electric tramway along the shore of the lake, and frequent communication over the lake “Staatsliche Bahn” from Territet there is a mountain railway past Glion and Caux nearly to the top of the Rochers de Naye (6710 ft.), while from Veytaux the Montreux-Bernois-Oberland railway mountains past Les Avants, pierces the ridge of the Col de Jaman by a tunnel, and so reaches (14 m.) Montbovon in the Gruyère portion of the upper Sarine valley. At first foreigners were attracted by the cheapness and good air of the region, added to the grape cure. As the delights of clear, cold weather in winter and of tobogganing (here called “lugging”) and skiing became appreciated, the higher hotels (such as Les Avants, Caux, Glion) were frequented at that season, as well as at other times. It is stated that in 1902 31,473 foreigners (in 1903, 39,493) visited Montreux, 7634 being Germans, 7327 English, and 5651 French. Montreux was not a Roman settlement, but otherwise its history is similar to that of Vevey.

MONTROND, CASIMIR, COMTE DE (1768-1843), French diplomatic agent, was the son of a military officer; his mother, Angélique Marie d'Aulus, comtesse de Montrond (d. 1827), was a royalist writer, said to be the author of the Troubadour bléarmois, a song which has the refrain “Louis, le fils de Henri, Est prisonnier dans Paris.” Casimir was imprisoned in 1794 in St Lazare, where he met the divorced duchesse de Fleury (née Franquetot de
Coigny), the "jeune captif" of André Chénier's famous verses. He bought his freedom and his own with 100 lous. They married and crossed to London, but the union proved unhappy, and they were divorced on their return to Paris.

Turning to the fashionable world, Casimir de Montrond became famous for his successes. He was the confidant and political agent of Talleyrand, and his inside knowledge of politics enabled him to make a large fortune on the Bourse. In 1809 he was disgraced for some imprudent comments on the imperial system, and exiled from Paris. After spending some time at Antwerp he removed to Spa, where he was on intimate terms with Pauline Borghèse, and in 1811 he returned to Antwerp; here he was arrested by Napoleon's orders and sent to the fortress of Ham. After a month's imprisonment he received permission to reside, under police supervision, at Châtillon-sur-Seine, where he presently escaped to England. He returned to France at the first Bourbon restoration, and during the Hundred Days was entrusted with a mission to Vienna to convert Talleyrand to Napoleon's interests, to see Metternich and Nesselrode, and to bring back if possible Marie Louise and the king of Rome. The second restoration restored him to his social triumphs, though he was supplanted in practice by Charles Marmont, on whom he accompanied him to Valencay and continued to help with his intrigues. He followed Talleyrand to London in 1832. Montrond returned to Paris some time before his death in 1843.

See H. Welschinger, "L'Ami de M. de Talleyrand," in the Revue de Paris (Feb. 1895); Lanzac de Laborie, La Domination française en Belgique (1895); and Amédée Pichot, Souvenirs sur M. de Talleyrand (1870).

MONTROSE, MARQUESS AND DUKES OF. David Lindsay, 5th earl of Crawford (c. 1440-1495), was created duke of Montrose in 1488 (the first dukedom conferred in Scotland on a person not of royal blood), as a reward for remaining loyal to James III. during the rebellion of Angus and Prince James. Montrose was deprived of his dukedom by James IV., but it was restored in 1489 for life only. On his death in 1495 the title therefore became extinct.

In 1505, William, 4th Lord Graham, whose wife Annabella Drummond was the duke's niece, was created earl of Montrose; and this title was held by his descendants till 1644, when James Graham, 9th earl, was created marquess of Montrose and earl of Kincardine. This was the celebrated marquess of Montrose (p.r.) of the Civil War, whose son and successor, James (c. 1631-1669), was known as "the Good Marquess." The latter refused to vote at the trial of his hereditary enemy the marquess of Argyll in 1661, admitting that he could not act impartially in such a matter; and the two noblemen afterwards became firm friends. The good marquess died in 1669, and was succeeded by his son James, 3rd marquess of Montrose (d. 1684). The 4th marquess, son of the last mentioned, who was also named James (d. 1743), was lord high admiral of Scotland in 1705, and lord president of the council in 1706. He was an ardent supporter of the Hanoverian succession; and he also favoured the union of Scotland with England, for his services in regard to which he was created duke of Montrose and marquess of Graham in 1707, becoming in the same year one of the first representative peers of Scotland in the parliament of Great Britain. He was one of the regents of the kingdom on the death of Queen Anne, and was appointed a secretary of state by George I. He took an active part in suppressing the Jacobite risings after the death of the Jacobite earl of Mar, and was keeper of the great seal of Scotland. He died in 1742. During his lifetime his son David was raised to the peerage of Great Britain with the title of Earl Graham; and on David's death without issue in 1731 this earldom passed under a special remainder to his brother William (c. 1710-1790), who on his father's death in 1742 succeeded to the dukedom also. William's son James, 3rd duke of Montrose (1755-1836), held office in Pitt's administrations in 1783 and 1804, and in that of the Duke of Portland in 1807. He obtained the annulment of the law prohibiting Highlanders from wearing the kilt. He was succeeded by his son James (1790-1874), who held office under the earl of Derby in 1852, and again in 1858 and 1866, and was father of Douglas Beresford Malise Ronald, 5th duke (b. 1852). In 1853 James Lindsay, 24th earl of Crawford, claimed the title of duke of Montrose on the ground that the patent granted to his ancestor David Lindsay in 1488 (see above) had not been effectively rescinded, but his petition was dismissed by the House of Lords.

MONTROSE, JAMES GRAHAM, MARQUESS OF (1612-1659), was born in 1612, and became 5th earl of Montrose (see above) by his father's death in 1626. He was educated at St. Andrews, and at the age of seventeen married Magdalene Carnegie, daughter of Lord Carnegie (afterwards earl of Southesk). Not long after the outbreak of the Scottish troubles in 1637 he joined the party of resistance, and was for some time one of its most energetic champions. He had nothing puritanical in his nature, but he shared in the ill-feeling aroused in the Scottish nobility by the political authority given by Charles to the bishops, and by Hamilton's influence with the king, and also in the general indignation at the scheme of imposing upon Scotland a liturgy which had been drawn up at the instigation of the English court and corrected by Archbishop Laud. He signed the Covenant, and was told off to suppress the opposition to the popular cause and for its maintenance in the country of the Gordons. Three times, in July 1638, and in March and June 1639, Montrose entered Aberdeen, where he succeeded in effecting his object, on the second occasion carrying off the head of the Gordons, the marquess of Huntly, as a prisoner to Edinburgh, though in so doing, for the first and last time in his life, he violated a safe-conduct.

In July 1639, after the signature of the treaty of Berwick, Montrose was one of the Covenanting leaders who visited Charles. This change of policy on his part, frequently ascribed to the fascination of the king's conversation, arose in reality from the nature of his own convictions. He wished to get rid of the bishops without making presbyters masters of the state. His was essentially a layman's view of the situation. Taking no account of the real forces of the time, he aimed at an ideal form of society in which the clergy should confine themselves to their spiritual duties, and the king, after being enlightened by open communication with the Scottish nation, should maintain law and order without respect of persons. In the Scottish parliament which met in September, Montrose found himself in opposition to Argyll, whose interests were the Presbyterian and national party, and of the middle classes. Montrose, on the other hand, wished to bring the king's authority to bear upon parliament to defeat this object, and offered him the support of a great number of nobles. He failed, because Charles could not even then consent to abandon the bishops, and because no Scottish party of any weight could be formed unless Presbyterianism were established ecclesiastically.

Rather than give way, Charles prepared in 1640 to invade Scotland. Montrose was of necessity driven to play something of a double part. In August 1640 he signed the Bond of Cumbernauld as a protest against the "particular and direct practising of a few," in other words, against the ambition of Argyll. But he took his place amongst the defenders of his country, and in the same month he displayed his gallantry in action at the forcing of the Tyne at Newburn. After the invasion had been crowned with success, Montrose still continued to cherish his now hopeless policy. On the 27th of May 1641 he was summoned before the Committee of Estates charged with intrigues against Argyll, and on the 8th of June he was imprisoned in Edinburgh Castle. When Charles visited Scotland to give his formal assent to the abolition of Episcopacy, Montrose communicated to him his belief that Hamilton was a traitor. It had indeed been alleged, on Clarendon's authority, that he proposed to murder Hamilton and Argyll; but this is in all probability only one of Clarendon's many blunders. (See S. R. Gardiner, Hist. of England, 1603-1642, x. 26.) Upon the king's return to England Montrose shared in the amnesty which was tacitly accorded to all Charles's partisans.

For a time Montrose retired, perforce, from public life. After the Civil War began in England (see Great Rebellion) he
Montrose—Mont St Michel

constantly pressed Charles to allow him to make a diversion in Scotland. Hamilton's impracticable policy of keeping Scotland neutral was now seen in the way of Charles's plans. But in 1644, when a Scottish army entered England to take part against the king, Montrose, now created a marquess, was at last allowed to try what he could do. He set out to invade Scotland with about 1000 men. But his followers deserted, and his condition appeared hopeless. Disguised as a groomsman, he started on the 18th of August with only two gentlemen to make his way to the Highlands. Highlanders had never before been known to combine together, but Montrose knew that most of the clans detested Argyll, and the clans rallied to his summons. About 2000 disciplined Irish soldiers had crossed the sea to assist him. In two campaigns, distinguished by rapidity of movement, he met and defeated his opponents in six battles. At Tippermuir and Aberdeen he routed Covenanting levies; at Inverlochy he crushed the Campbells, at Auldearn, Alford and Kilsyth his victories were obtained over well-led and disciplined armies. At Dundee he extricated his army from the greatest peril, and actually called his men off from the sack that had begun—a feat between the power of any other general in Europe. The fiery enthusiasm of the Gordons and other clans often carried the day, but Montrose relied more upon the disciplined infantry which had followed Alastair Macdonald from Ireland. His strategy at Dundee and Inverlochy, his tactics at Aberdeen, Auldearn and Kilsyth furnished models of the military art, but above all his daring and constancy marked him out as the greatest soldier of the war, Cromwell alone excepted. His career of victory was crowned by the great battle of Kilsyth (Aug. 15, 1645). Now Montrose found himself apparently master of Scotland. In the name of the king, who now appointed him lord-lieutenant and captain-general of Scotland, he summoned a parliament to meet at Glasgow on the 20th of October, in which he no doubt hoped to reconcile loyal obedience to the king with the establishment of a non-political Presbyterian clergy. That parliament never met. Charles had been defeated at Naseby a month before, and Montrose must continue his army till he had again a king to proclaim. David Leslie, the best of the Scottish generals, was promptly despatched against Montrose to anticipate the invasion. On the 12th of September he came upon Montrose, deserted by his Highlanders and guarded only by a little group of followers, at Philphaugh. He won an easy victory. Montrose cut his way through to the Highlands; but he failed to organize an army. In September 1646 he embarked for Norway.

Montrose was to appear once more on the stage of Scottish history. In June 1649, burning to revenge the death of the king, he was restored by the exile Charles II. to the now nominal lieutenancy of Scotland. Charles however did not scruple shortly afterwards to disavow his noblest supporter in order to become a king on terms dictated by Argyll and Argyll's adherents. In March 1650 Montrose landed in the Orkneys to take the command of a small force which he had sent on before him. Crossing to the mainland, he tried to use the fortress of Inverlochy. 27th of April he was surprised and routed at Carbisdale in Ross-shire. After wandering for some time he was surrendered by Macleod of Assynt, to whose protection, in ignorance of Macleod's political enmity, he had entrusted himself. He was brought a prisoner to Edinburgh, and on the 20th of May sentenced to death by the parliament. He was hanged on the 21st, with Wishart's laudatory biography of him put round his neck. To the last he protested that he was a real Covenanter and a loyal subject.

The principal authorities for Montrose's career are Wishart's Rerum Scoticarum, 1649; Leslie, History of Scotland, 1664; Patrick Gordon's Short Account of Brian's Distemper (Spalding Club); and the comprehensive work of Napier, Memorials of Montrose, is abundantly documented, containing Montrose's poetry, in which is included his celebrated lyric "My dearest and only love."

Montrose, a royal, municipal, and police burgh and seaport of Forfarshire, Scotland. It is situated 30½ m. N.E. of Dundee by the North British railway and is also connected with the Caledonian railway company's system by a branch to Dunbean. Pop. (1901), 12,427. The town occupies a considerable area on a sandy peninsula, and is bounded on the E. by the North Sea, on the N. by the North Esk, on the S. by the South Esk, and on the W. by Montrose Basin, a large depression, about 7 m. in circuit. The reclamation of the Basin has been attempted, but an embankment constructed by Dutch dikers for this purpose was demolished in a few hours by a storm. In the mouth of the channel of the South Esk lies the island of Rossie, or Inchbrayock (pop. 160), which in 1829 was connected with the burgh by means of a suspension bridge 432 ft. long and by a drawbridge with the south bank near the fishing village of Ferryden (pop. 1330). The harbour lies between the suspension bridge and the sea, and is provided with a wet dock. The links form one of the best golf-courses in Scotland and are played over by several clubs. Besides the staple industry of flax-spinning, there are manufactures of linen, canvas, sheeting, starch, soap, chemicals, rope and manures, while iron-founding, tanning and brewing are also carried on. The fisheries are of very considerable importance and the shipping is usually brisk. There is a large trade, especially in timber (the chief import), mainly with Baltic ports and Canada. The parish church is a plain structure, but has a handsome steeple 200 ft. high. The principal buildings include the town-hall, the academy on the links, dating from 1820, though its predecessor belonged to the 16th century; the museum, Doward's house of refuge, erected in 1839; the infirmary and the royal asylum at Sunnyside on the outskirts to the north-west. Panmure barracks are not far from the wet dock. In High Street are statues to Sir Robert Peel and Joseph Hume. Montrose is governed by a provost, bailies and council, and unites with Arbroath, Brechin, Forfar and Inverbervie (the Montrose burghs) in returning one member to parliament, a district group that was represented for many years by John Morley. Montrose received its charter from David I., and was made a royal burgh in 1352. It was destroyed by fire in 1244. Here Edward I. accepted John Balliol's surrender of the kingdom on the 10th of July 1296. Sir James Douglas sailed from the pier in 1200 buoy for the Holy Land with the noble Bruce; and here, too, the Old Pretender embarked in 1716 for France after the failure of his cause. In 1745 the town threw in its lot with the Hanoverians, a fact which lent zest to the daring capture of the "Hazard" sloop of war off Ferryden, by Captain David Ferrier of Brechin, a thorough-going Jacobite.

Mont St Michel, a rocky islet of western France, off the coast of the department of Manche, some 6 m. N. of Pontorson. Pop. (1906), 238. It forms a towering mass of granite about 3000 ft. in circumference and 165 ft. in height, rising near the mouth of the Couesnon nearly a mile from the shore, to which it is united by a causeway. The fortress-abbey to which Mont St Michel owes its fame stands upon the more precipitous side of the islet towards the north and west, the sloping portion towards the east and south being occupied by houses. A strong machioculated and turreted wall surrounds the rock, running along its base on the south, ascending half-way up on the north. The chief cliff is defended by a flat wall close to the abbey wall, and again descending on the west. The northern and oldest portion of the ramparts dates from the 13th century; the single gateway by which they are pierced is on the south and is a good example of the military architecture of the 15th century. The single street of the island curves from the gateway up to the abbey, ending in flights of steps leading to the donjon or château. It is bordered by old houses, among which is one built by Bertrand du Guesclin in 1366, and contains a parish church of the 15th century. The abbey itself consists of an assemblage of buildings in three storeys upon massive foundations around the church, the most important portion, the Merveille, extending to the north. The floor of the church, built partly on the rock, partly upon foundations, and, at the east end, over a crypt, is on a level with the uppermost storey of the monastic buildings. To the north of and below the apse lies the group of buildings known as the Bénédict Chaise. It comprises the châtelet (17th century), a square entrance structure strengthened by flanking turrets and machicolation, the adjoining guard-room (13th century) with the salle
des officers above it, and behind all the Tour Perrine. The Mervelle (1203-1264) consists of two continuous buildings of three stories, that on the east containing, one above the other, the hospitium (asumôberia), refectory and dormitory, that on the west the cellar, knights' hall (salle des chevaliers) and cloister. Of the apartments, all of the finest Gothic architecture, the chief are the refectory, divided down the centre by columns and lighted by large embrasured windows, and the knights' hall, a superb chamber, the vaulting of which is supported on three rows of cylindrical pillars. The cloister, one of the purest and most graceful works of the 13th century, is surrounded by double lines of slender columns carrying pointed arcades, between which delicate floral designs are carved. The exterior wall of the Mervelle is of remarkable boldness; reaching a height of 105 ft., it is supported by twenty buttresses and pierced with a variety of openings. The church, which rises high above the buildings clustering round it, consists of transsepts and four bays of the nave of Romanesque architecture and of a fine choir (1450-1521) in the Flamboyant Gothic style with a triforium surmounted by lofty windows. This choir replaced one which collapsed in 1431. In 1776 three of the seven bays of the nave were pulled down, and soon after the incongruous western front was added. The finest part of the exterior is the choir, which is ornamented with a profusion of carved pinnacles and balustrading. The central tower terminates in a Gothic spire surmounted by a gilded bronze statue of St Michael.

Mont St Michael was a sacred place from the earliest times. In the 8th century an oratory was established there by St Aubert, bishop of Avranches, in obedience to the commands of an apparition of St Michael. The place soon became a noted resort of pilgrims, not only from all parts of France, but also from Great Britain, Ireland and Italy. In 666 Richard I., duke of Normandy, founded in place of the oratory a Benedictine monastery, which in the succeeding century received a considerable share of the spoils and revenues of the abbey of Westminster, and became an English foundation. In 1305 the monastery was burnt by the troops of Philip Augustus, who afterwards furnished large sums for its restoration (La Mervelle). St Louis made a pilgrimage to Mont St Michel, and afterwards supplied funds which were spent on the fortifications. A garrison and military governor subordinate to the abbot were also installed. During the last thirty years of the Hundred Years' War the abbey offered a persistent resistance to the English. In 1460 Louis XI. instituted the Order of St Michel, which held its meetings in the salle des chevaliers. During the Wars of Religion, the Huguenots repeatedly made unsuccessful attempts to seize the fortress, which opened its gates to Henry IV. in 1595 after his abjuration. In 1592 the Benedictine monks of Mont St Michel were replaced by monks of the Congregation of St Maur. In the 18th and 19th centuries the abbey was used as a prison for political offenders, serving this purpose until 1863, when an extensive restoration, begun in 1838, was resumed. The building is the property of the Commission of Historical Monuments, which has carried on the work of restoration with great architectural and antiquarian ability.

MONTserrat, or Monserrat, a remarkable mountain and monastery in north-east Spain, 30 m. N.W. of Barcelona. The mountain is of grey conglomerate; its main axis trends from W.N.W. to E.S.E., and its circumference is about 18 m. The loveliest point is the Turó de San Jeronimo, also called Mirador and La Miranda (4070 ft.), which commands a view of the Pyrénées, and the Mediterranean Sea as far as the Balearic Islands. On the east the base of the Montserrat is washed by the river Llobregat. The Montserrat consists of jagged pinnacles and spires (pelhacs) rising abruptly from the base of the mass, which is washed by many ravines, and amongst with steep precipices. It is the mons serratus of the Romans, the monte serrado of the Spaniards, and is thus named either in allusion to its jagged appearance, like the teeth of a saw, or because it is split, as if sawn by the vast fissure of the Valle Maio, which extends from north-west to east. This occurred, say the Spanish legends, at the time of the Crucifixion, when the rocks were rent. In medieval German legends, which located here the castle of the Holy Grail, the mountain is called Monsalvatge, a name analogous to the modern Catalan form Montserrat "sacred mountain." From Monistrol, a village on the north-east, with a station on the Barcelona-Lérida railway, the monastery can be reached either by the carriage road built in 1857, or by the mountain railway opened in 1892. The ascent is also frequently made by a bridle path from the village of Collbató, on the south-west, where there are some interesting caverns.

The monastery stands 2910 ft. above sea-level upon a narrow platform on the edge of the Valle Maio. It owes its existence to an image of the Virgin, said to have been carved by St Luke, and brought to Barcelona by St Peter in A.D. 30. When the Moors invaded the province in 717 the image was taken to Montserrat, where a Benedictine convent appears to have already existed, and hidden in a cave. In 880 Gondeimar, bishop of Vic, was attracted to the cave by sweet sounds and smells, and there found the image, which he determined to take to Barcelona. But at a certain spot on the mountain the image refused to proceed farther; there it was consequently deposited, and a chapel was erected to contain it. Round the chapel a nunnery was built, and in 976 this was enlarged and converted into a second Benedictine convent. The old monastery (monasterio antiguo) is chiefly in ruins. The cloisters, belfry and part of the church were Gothic of the 15th century. The church of the new monastery (monasterio actual) was built in Renaissance style under Philip II. (1560-1592); in 1811 it was partially burned, and in 1880 a Romanesque apse was added. New buildings for the monks were erected under Ferdinand VII. (1784-1833), but partly unfinished. During the Napoleonic wars (1808-14) it was despoiled of the vast treasures which had accumulated during the middle ages. In 1835, as a result of the Carlist insurrection, the convent was deprived of its estates and the number of monks reduced to about twenty. The monks are largely occupied by the management of a school of sacred music. The church of the monastery, which by a grant of Pope Benedict XIII. had been an independent abbey since 1410, was made subject to the bishops of Barcelona.

Nuestra Señora de Montserrat, Patrona de Cataluña ("Our Lady of Montserrat, Patron Saint of Catalonia"), is one of the most celebrated images in Spain, and her church is visited annually by more than 60,000 pilgrims. The image is small, black and carved of wood, but possesses magnificent robes and jewels. In September 1888 it was solemnly crowned by Leo XIII., who sent a crown from Rome for that purpose. As the celebrity and sanctity of the image increased, the number of pilgrims to Montserrat (monástirio antiguo) laid his sword upon the altar of the Virgin, and, placing himself under her protection, started from Montserrat to begin his new life. Many eminent Spaniards, weary of the French, have retired to Montserrat, which is considered as the most secluded sanctuary on earth. Some preferred solitary hermitages perched among the rocks. Of these there were fifteen, eleven of which once formed a via sacra, ending at the summit of San Jeronimo. They were destroyed by the French, but the ruins of some remain. There are also caves in the mountain, some of which were formerly occupied by monks. The most celebrated of these are the cave of the Virgin, in which the santa imagen remained hidden until found by Gondeimar, and the cave of Fray Juan Caro, a notorious Gypsy, who ended his days in the practice of revolting penances at Montserrat.

MONTserrat, an island in the British West Indies, one of the five presidencies in the colony of the Leeward Islands. Pop., mostly negroes (1901), 12,215. It lies 27 m. S.W. of Antigua, in 16° 25' N. and 62° 7' W.; is 11 m. long and 7 m. broad, and has a total area of 323 sq. m. The island is a cluster of rugged volcanic peaks rising from the Caribbean Sea, their summits clothed with forests; the still active Soufrière (3000 ft.) in the south being the highest point. The average temperature is 81° F., the hottest weather being usually tempered by cool sea breezes; the rainfall averages 94 in. per annum. There is a plentiful supply of water, and the roads are macadamized and well drained. The principal products are sugar and raw and concentrated lime-juice. Minerals are also found. Montserrat has a local legislature of six members, nominated by the Crown, and sends representatives to the general legislative council of the colony. Education is compulsory, and the majority of the schools are managed by the Church of England, to which most of the islanders belong; but the Wesleyans and the Roman
Catholics also support schools. Plymouth (pop. 1461), the chief town, stands on an open seacoast on the south-west coast.

The island was discovered by Columbus in 1493, who named it after Monserado, a mountain in Spain. It was colonized by the British under Sir Thomas Warner in 1632, and was taken by the French in 1662. Restored to the British in 1668, it capitulated to the French in 1782, but was again restored in 1784.

MONTT, MANUEL (1809-1888), Chilean statesman, was born on the 5th of September 1809. He had a distinguished career as a scholar, and was introduced into public life during the presidency (1831-1841) of Arrieto by Diego Portales. Montt distinguished himself by his courage in the crisis that followed upon Portales’ assassination in 1837, though only holding a subordinate post in the government, and afterwards he held several ministerial offices, and during the presidency (1841-1851) of Bulnes he became minister of justice and public instruction, and later of the interior. He was elected president in 1853 and again in 1856, and though the Liberals chafed under his rule, and two revolutions, in 1857 and 1859, took place during his administration, he governed Chile with an energy and wisdom that laid the foundation of her material prosperity. He was ably assisted by his minister of the interior Antonio Vars, and it was from the union between the two men that the revolutionary faction, the Montt-Varistas, took their name. His presidency was marked by the establishment of railways, telegraphs, banks, schools and training-colleges. On giving up his post in 1861 he became president of the Supreme Court of Justice, a position which he held up to his death on the 20th of September 1880. His son Jorge (b. 1846) was president of Chile in 1891-1896, and a younger son, Pedro (d. 1910), in 1900-1910.

See P. B. Figueroa, Diccionario biográfico de Chile, 1550-1887 (Santiago, 1888); and J. B. Suarez, Rasgos biográficos de hombres notables de Chile (Valparaíso, 1886).

MONTUCLA, JEAN ÉTIENNE (1725-1799), French mathematician, was born at Lyons on the 5th of September 1725. In 1745 he published an anonymous treatise entitled Histoire des recherches sur la quadrate du cercle, and in 1758 the first part of his great work, Histoire des mathématiques, the first history of mathematics worthy of the name. He was appointed intendant-secretary of Grenoble in 1758, secretary to the expedition for colonizing Cayenne in 1764, and “premier commis des bâtiments” and censor-royal for mathematics in 1765. The Revolution compelled the intendant to leave Montucla and the house in which he had erected the monumentum, the to which he had donated his whole property. The offer in 1795 of a mathematical chair in one of the schools of Paris was declined on account of his infirm health, and he was still in straitened circumstances in 1798, when he published a second edition of the first part of his Histoire. In 1778 he re-edited Jacques Ozanam’s Récitations mathématiques, afterwards published in English by Charles Hutton (4 vols., London, 1803). He died on the 18th of December 1799. His Histoire was completed by J. J. Le F. de Lalande, and published at Paris in 1799-1802 (4 vols.).

MONTYON, ANTOINE JEAN BAPTISTE ROBERT AUGET, BARON DE (1773-1820), French philanthropist, was born in Paris on the 23rd of December 1773. His father was a maître des comptes; he was educated for the law, and became advocate at the Châtelet in 1755, master of requests to the council of state in 1760, and intendant successively of Auvergne, Provence, and La Rochelle. He had repeatedly shown great independence of character, protesing against the accusation of Caradeuc de La Chalotais in 1766, and refusing in 1777 to suppress the local council of this town when it protested against the appointment of a councillor of state in 1775 by the influence of Louis de Bourbon, duke of Penthièvre, and in 1780 he was attached to the court in the honorary office of chancellor to the comte d’Artois (afterwards Charles X.). He followed the princes into exile, and lived for some years in London. During the emigration period he spent large sums on the alleviation of the poverty of his fellow immigrants, returning to France only at the second restoration. Between 1780 and 1787 he had founded a series of prizes, the awards to be made by the French academy and the academies of science and medicine. These prizes fell into abeyance during the revolutionary period, but were re-established in 1815. Montyon died on the 29th of December 1820, bequeathing 10,000 francs for the perpetual endowment of each of the following prizes: for the discovery of the means of rendering some mechanical process less dangerous to the workman; for the perfecting of any technical improvement in a mechanical process; for the book which during the year rendered the greatest service to humanity; the "prix de vertu" for the most courageous act on the part of a poor Frenchman—the awards being left as before to the learned academies. He also left 10,000 francs to each of the Parisian hospitals.

Montyon wrote a series of works, chiefly on political economy: Éloge de Michel de l’hôpital (Paris, 1777); Recherches et considérations sur la population de la France (1778), a share of which is attributed to his secretaries, Moheau, Rapport fait à Louis XVIII. (Guimbaud, 1796), in which he maintained in opposition to Calonne’s Tableau de l’Europe that France had always possessed a constitution, which had, however, been violated by the kings of France; L’état statistique du Tarnin (1811); and Particulariés... sur les duties des finances in France (1812).

See Lacleret, “Discours sur M. Montyon,” in the Recueil de l’académie (1820-1829); Quérard, La France littéraire, vol. vi. (1854); and further, J. Labour, M. de Montyon d’après des documents inédits (Paris, 1884); and especially L. Guimbaud, Angé de Montyon (1899).

MONUMENT (Lat. monumentum or monumentum; from monere, to advise, bring to mind, remind; the German equivalent is Denkmal), literally that which serves to keep alive the memory of a person, an event, or a period. The word is thus applied to a column, statue, building erected for that particular purpose, as "The Monument" (i.e. of the Great Fire) in London; to all the various memorials which man throughout the ages has raised over the buried dead, the bars and carvings of prehistoric times, the representation of the living figure of the dead, brasses, busts, &c., or the varying forms, allegorical or otherwise, taken by the tombstones of the modern cemetery. In a wider sense "monument" is used of all survivals of a past age, in which sense it may include all the vestiges of prehistoric man, dolmens, menhirs, remains of lake-dwellings, stone-circles, and the like, buildings large and small, cities, castles, palaces, and examples of domestic architecture, which have any interest, historic or artistic, as well as movable artifices or archaeological treasures, which exist in private or public collections, or which are discovered by excavation. In a more restricted sense the word "monument" is also applied to a comprehensive treatise on any particular subject—such as the Monumenta typographica, or an historical collection such as the Monumenta Germaniae historica. In the English law of conveyancing a "monument" is an object fixed in the soil, whether natural or artificial, and referred to in a document, and used as evidence for the delineation of boundaries or the situation of a particular plot of land, &c.

For a description of various kinds of monuments see such articles as ARCHÆOLOGY; STONE MONUMENTS; EFFIGIES, MONUMENTAL; BRASSES; SCULPTURE; many particular monuments, such as Stonehenge, are treated under their respective names, or in the articles on the towns, &c., in which they stand.

The present article deals with the preservation, by government action, local or central, of the evidences and remains of past history and civilization, and, incidentally, with similar action extended to sites and places of natural beauty and interest, which the Germans call Naturdenkmäler, natural monuments.

The important work of G. Baldwin Brown, The Care of Ancient Monuments, published in 1865, is probably the only book in English on this subject. It contains a most ample bibliography for each country and gives many references to various periodicals in different languages. In 1897 was issued a report (C. 8443, Miscell. Reports, 2) from British representatives abroad as to "the statutory provisions existing in foreign countries for the preservation of historical buildings." Reference also should be made to The Care of Natural Monuments (1900), by H. Conwentz, Prussian State Commissioner for the Care of Natural Monuments.

The chief question at issue is, how far does the national
artistic or historic interest of a monument, in the widest sense of the word, justify the interference of the state with the right of a private owner, whether corporate body or individual, to do what he likes with his own? Nearly every European country other than the United Kingdom has given a decided answer to this question. It may be noticed, as showing the extreme reluctance to state interference in the United Kingdom, that a clause, laying on an owner of a monument, scheduled under the Monument Act 1882, the obligation of offering it for purchase to the state if he wished to destroy it, was struck out of that act.

The main lines followed by legislation or regulation for the preservation of monuments may be briefly indicated. Central organizations of commissions and conservators, with a staff of architects, inspectors, and archaeological or artistic experts for consultation, are established. These have large legal powers of enforcing their decisions, or may act chiefly by advice or persuasion. The national treasures are catalogued and scheduled, and the value estimated in an exhaustive inventory, in many cases supplemented by local inventories. In many cases, unfortunately, a valuable monument has been destroyed through ignorance of its value. A special form of inventory, carrying with it legal consequences, is that known as the classé system; of this form the French is the typical example. In this only the outstanding monuments find a place, and such either become national property altogether, or the protection and preservation is undertaken by the state, or may be left in the hands of the private owner; but in any case the monument cannot be destroyed, restored or repaired without the consent of the central authority. The classé system has been criticized as tending to depreciate the consideration paid to such monuments as do not appear in the list—monuments non-classés. The British Monument Acts adopt a narrow kind of classé in the schedule attached to the 1882 act. Most states have powers of expropriation or compulsory purchase of private property on grounds of public utility and architectural law, or to prevent execution—a case in the case of the compulsory purchase of land for railways. The majority of states have made the protection of monuments such a matter of public utility. Further, the exportation of artistic or historic treasures, i.e., movable monuments, has been controlled by the state, notably in the case of Italy and Greece, Turkey and Egypt. Connected with this side of the question is the control by the state of excavations undertaken by private persons, even on their own property. In Germany considerable protection is effected by the powers given to municipalities to make by-laws, respecting not only the preservation of the monuments, but also the erection of new buildings that may interfere with the monuments or with the general characteristic appearance (Stadtbild) of the town. This is also the case in Italy, where there are frequent regulations as to town-planning (piano regolamentato).

The following is a brief account of the measures adopted in the principal countries of the world for the preservation and protection of their artistic and historic treasures.

United Kingdom.—There are four acts: the Ancient Monuments Protection Act of 1882, 1900 and 1910, and the Ancient Monuments Protection (Ireland) Act 1892. The act of 1882, due primarily to Lord Avebury, then Sir John Lubbock, provided that a list of monuments 1 in Great Britain and Ireland should be made to which the act was to apply; the number of these monuments was sixty-eight, all being of the kind known as prehistoric (barrows, stone-circles, dolmens, &c). An owner of one of these scheduled monuments may by deed place it in the guardianship of the commissioners of works, who are then responsible for its preservation and can protect it even against the owner. The commissioners may purchase any of the scheduled monuments, but only by agreement, the compulsory clauses of the Lands Clauses Consolidation Acts being expressly excluded, though any purchase is to be made under these acts. An owner of any monument other than those scheduled may place it in the care of the commissioners. The funds for the working of the act are to be provided by parliament, and an inspector of ancient monuments was appointed. General Pitt-Rivers, the first inspector appointed, found that without compulsory powers the act was useless, and for many years did not draw his official salary. After his death in 1900 the office was left unfilled until 1910. The act of 1892 applied to Ireland only, and is supplementary to that of 1882, which applied to the whole of the United Kingdom. The Irish act gave to the commissioners of public works in Ireland powers—only to be exercised with the consent of the owner—of applying the act of 1882 to any monument possessing such public interest as might render it worthy of preservation. It is to be noticed that after the disestablishment of the Irish Church certain unused churches of artistic or historic interest were placed in the charge of the commissioners as national monuments, with a sum of £50,000 to defray expenses. The Irish commissioners have therefore monuments in their care other than those scheduled in the acts, and may apply towards the expenses of the preservation of the scheduled monuments any surplus over from the fund above mentioned. The act of 1900 applied the Irish act to Great Britain, but the powers have not been exercised by the first commissioner of works. The act also gave the powers of the act of 1892 to county councils, allowed the authorities, local or central, to make arrangements for the preservation of monuments with owners or others, including societies, and to receive subscriptions for the same object, and also provided for public access to such monuments as are in the guardianship of the commissioners under the act. The acts of 1892 and 1900, though allowing buildings of historic or other interest to be placed under the care of the commissioners, exclude buildings occupied as a dwelling-place by any person other than a caretaker and his family. The act of 1910 gives to the commissioners of works power to acquire by bequest buildings of historic or artistic interest, and in the case of churches, has the power to acquire such by gift or purchase, and the act of 1882 had given power by bequest also, but only referred to prehistoric remains. The London County Council possesses powers of purchasing by agreement any building of historic or other interest under a General Powers Act of 1898, and exercised these in 1900 by purchasing a 17th century house in Fleet Street (known as Cardinal Wolsey's palace). It will be seen that the United Kingdom possesses no official commission, no conservators, no consultative official body, and no compulsory powers of expropriation. The acts dealing with the subject are entirely permissive. Towards the making of a national inventory the first step taken was the appointment in 1908 of three royal commissions, for England, Scotland and Wales respectively, "to make an inventory of the ancient and historical monuments and constructions connected with or illustrative of the contemporary culture, civilization and conditions of life of the people from the earliest times"; to the year 1700 in the case of England; 1707 in the case of Scotland; for Wales no date is specified; and "to specify those which seem worthy of preservation." The Housing, Town Planning, &c Act 1909, §45, and the Development and Road Improvement Funds Act, 1909, excepts the sites of ancient monuments or of other objects of historical interest from compulsory acquisition for the purposes of those acts. The Finance Act 1896, §20, granted a qualified exemption from estate duty to pictures, prints, books, MSS., works of art, scientific collections and other things not yielding income, as appear to the Treasury to be of national, scientific or historic interest; this exemption only extends where such property is settled to be enjoyed in kind in succession by different persons; if the property is sold or is in the possession of a person competent to dispose of it, it becomes liable to estate duty. The Finance Act 1909 extends the exemption to legacy and succession duty, removes the restriction to settled property, and adds "artistic" to "national and historic interest." The Committee for the Survey of the Memorials of Greater London, supported by the London County Council, has begun a complete register and survey of the historic buildings of London. Apart from the numerous national and archaeological

---

1 The names of the monuments so scheduled are given in an appendix to Sir R. Hunter's Lecture on the Preservation of Places of Interest and Beauty (1907).
societies, whose proceedings contain invaluable accounts of practically every monument of interest throughout the kingdom, there are two societies directly formed with the object of monument preservation in its widest sense, the Society for the Protection of Ancient Buildings, founded in 1837, and the National Trust for Places of Historic Interest and Natural Beauty, constituted in 1894 under the Joint Stock Companies Acts for the purchase and preservation of sites and buildings, which it can hold in perpetuity for the benefit of the public. In 1907 the latter was dissolved and re-incorporated as a statutory body by the National Trust Act 1907. It possesses twenty-eight properties, amounting to 2000 acres, and twelve interesting buildings.

India.—The Archaeological Survey of Upper India was established in 1862, with a director-general at its head, and surveys for other parts of India were also begun later. The chief object of these was the making of an inventory, and the preservation of the monuments was neglected. In 1878 a curator of ancient monuments was appointed. A period of activity with regard to monument preservation set in during the vicerecy of Lord Curzon; this culminated in the Ancient Monuments Preservation Act 1878, which provided for the protection of monuments. The government of any province may declare any monument to be a "protected monument within the meaning of the act," and when so declared no one may injure, remove or alter it under penalty of a fine or imprisonment. This, however, does not apply to the owner, except when the government has, by purchase or gift, or by taking over the guardianship of the monument, assumed the duty of preserving it. This assumption of guardianship is by agreement with the owner. Power of expropriation under the Land Acquisition Act 1894 is given if a monument protected under the act is threatened with destruction or injury, or if an owner refuses to come to an agreement with the authority for its guardianship. The act includes movable antiquities, and the governor-general in council can prohibit their exportation. Control over excavations is also given.

Egypt.—A Commission of Egyptology (Comité permanent d'Egyptologie) has the care of the monuments of early Egyptian civilization. The monuments of the Arab occupation are in the charge of a separate commission (Comité de conservation des monuments de l'art arabe). The Commission of Egypt issued decrees under khedival decrees of 1883, 1897 and 1899. By the first the state claims control over all antiquities and declares the contents of the Giza (Gizeh) Museum, now the National Museum of Egyptian Antiquities, and of any future collection, to be the property of the state and inalienable. The second decree penalizes any injury to monuments or attempt to appropriate a monument belonging to the state. The third deals with excavations; permission must be granted by the director-general of museums; objects discovered belong to the state and must go to the museum, but a part of the objects will be granted to the discoverer under special regulations, the government reserving the right to special objects with compensation for the expense of excavation.

France.—The Commission des monuments historiques was established in 1837. It is attached to and acts through the department of the minister of public instruction and of the fine arts, who is the president of the commission. There are thirty members, partly nominated by the minister out of names selected by the commission, partly ex officio, such as the directors of civil buildings and national palaces and of public worship. The buildings which these officials control are, however, not directly under the commission. The presence of a certain number of deputies on the commission secures its representation in the legislature. Upon the commission fall the following duties: (a) The classement or selection of the monuments of national interest, artistic, historic, or both, for the schedule of protected monuments. A particular portion of a building, such as a door, window, &c., may be alone protected. (b) The restoration and repair of the monuments so classed. (c) A general power of giving advice and watching the monuments of the country as a whole. The commission has the charge of the Musée Cluny, and is also the centre for all inquiries, reports, &c. The official staff of the commission consists of four general inspectors, one of whom, since the Monument Act of 1887, has charge of the movable monuments, and of forty architects, who have a subordinate staff of inspectors of works. Since 1830 a sum has been voted yearly for the finances of the commission. The largest sum (£120,000) that has appeared in the budget was voted in 1866; there are, however, other sources of revenue available.

The Monument Act of 1887.—This, together with certain administrative decrees, gave legal powers to the commission, which it had hitherto lacked, or had only been able to enforce by a difficult process of expropriation if owners, whether private or public, of monuments classés objected to the work of the commission. If a monument classé belong to the state or is under the administration of a minister other than the minister of public instruction and fine arts, or if it belong to any public body, such as a department or commune in whose hands the churches mainly lie, the consent of these controlling bodies must be given, otherwise the decision is left to the conseil d'État. If the owner be a private person, his consent is also necessary to the classement. If he refuses, the minister may expropriate the monument by a decree for purchase, which must have the consent of the conseil d'État. Once the expropriation is decreed, it cannot be destroyed even partially, and no repairs or other work will be effected upon it without the consent of the minister. An action, for damages only, lies against a person infringing the law in this respect. The act deals also with the classement and protection of movable objects of national interest, historic or artistic, but only if they belong to the state, when they cannot be alienated, or to public bodies, when the consent of the minister is required for repairs or alienation. The act does not affect movables belonging to private persons. Owing to the numerous thefts from churches, museums, and other places, which attracted particular attention in 1896, proposals have been made for the better protection of such objects, as well as of those in private collections, by gathering together the objects at present scattered in churches, &c., into provincial and local museums, and also by charging an entrance fee for museums, &c. With regard to the discovery of monuments by excavation works or accident, the minister must receive immediate notice from the mayor of the commune through the prefect of the department, and will decide what is to be done. If such discoveries are of a public character, they may proceed to expropriation. The act applies to Algeria. Here all objects of archaeological or artistic interest are reserved to the state, if on ground belonging to the government or granted by it to public bodies or private persons or in military occupation. The act is similarly extended to all French protectorates. Tunis has more stringent regulations; for by a decree of the bey, 1886, the consent of the owner to the classement of a monument is not required, and penalties under the French penal code attach to infringements.

There is a strong feeling in France as to the protection and preservation of sites of natural beauty. A Société pour la protection des paysages was founded in 1901, and in 1904 the minister of public works issued a circular to the government engineers emphasizing the obligation of preserving and, if possible, enhancing the natural beauties of any locality in which public works were being carried out. An act (Loi organisant la protection des sites et monuments naturels de caractère artistique) was adopted in 1906, extending a protection to such sites analogous to that under the Monument Act (Appendix B in Sir R. Hamer's Lecture, already cited, gives the regulations under this measure).

A law of 1910 prohibits the affixing of bills or advertisements on monuments and sites officially recognized as historical and in sites recognized as picturesque by the law of 1906. The prefect also fixes a zone near such sites or monuments within which advertisement is prohibited.

Societies, both national and local, are numerous and active in France, but the centralizing policy does not favour any close working with the commission. The most important are the Société nationale des antiquaires de France, founded in 1804, and the Société française d'archéologie pour la conservation et
The Superior Council of Antiquities and Fine Arts, created by the law of 1907, consists of 21 members; it is divided into three sections of 7 members each for antiquities, medieval and modern art, and contemporary art respectively. All the members of each are nominated by royal decree, and so are three members of the third, being elected, one by the architects, one by the sculptors, and one by the painters of Italy. This is an advisory body. The minister presides, and the director-general can be present and has a vote. The administrative organization under the director-general consists of the divisional superintendencies (each having a group of provinces under it) divided into three categories: (a) 18 superintendencies of monuments (preservation, administration, and surveillance of monuments even in private hands); (b) 14 superintendencies of archaeological excavations and museums (with control of objects in private hands and of the offices for exportation); (c) 15 superintendencies of galleries, medieval and modern museums and objects of art. Under each superintendent is a staff of directors of monuments, museums and galleries, of inspectors, architects, secretaries, custodians, &c.

The nominations to the superior grades are by competition. There are offices for the examination of objects before exportation in those towns in which there reside a superintendent of monuments or a director of a gallery or a museum in which it is necessary. The official organizations are assisted by (a) honorary inspectors, nominated by royal decree in any commune or circornado where it may seem advisable; (b) provincial commissions, meeting in the chief town of each province, composed of not less than 7 members, nominated by royal decree, and including of right the superintendents, and meeting normally twice a year.

The monuments within the purview of the act of 1907 and its administration comprise all movable (including MSS., incunabula, rare engravings and coins) and immovable objects of artistic value and interest, so long as these are not less than fifty years old nor the work of living persons. Such objects, if they belong to the state, a province, a commune, a religious corporation or any recognized corporation (ente morale), cannot be parted with at all, except as from one such body to another, and this only with the leave of the ministry; and the authorities of such bodies must present to the ministry an inventory of such objects. Nor may repairs or alterations be made to them without the consent of the ministry, which has the right to interfere by regulations (such as, e.g., the prohibition of the use of tapers, &c., which are liable to damage a picture) for the preservation and restoration (and in extreme cases even the removal) of such objects, if necessary, the latter being at the expense of the body to which they belong in so far as it can afford it. Any private person owning or possessing any object falling under the law, the importance and interest of which has been notified to him as the regulations provide, cannot transfer his property in or abandon his possession of it without informing the ministry, which has the right of pre-emption within two months (or four in case of financial pressure owing to many simultaneous offers) at the price for which he has contracted to sell it; and, if it is subject to damage and the proprietor will not provide for its repair, it may be expropriated by the state, by a province or commune—or even by bodies which have legal personality and aim at the preservation of such objects for the public enjoyment. It has not yet been possible, however, to secure the right of search nor of public access; so long as an object is well kept up by the owner, he may refuse the right of access except to the officials.

The exportation of objects of importance is forbidden, even if their importance has not been notified to the owner, who is under the obligation to advise the government of his intention to export, having the right of pre-emption within two or four months, as the case may be; and even if the government does not purchase the object, it may still return it to the proprietor, forbidding him to export it. The objects exported are subject to a progressive tax, with a maximum of 20%. Objects temporarily imported from foreign countries, and re-exported within five years, are not subject to tax. Temporary exportation, if
permitted, is allowed on deposit of the tax; and if objects of importance are allowed to be sent from one part of Italy to another (especially to the islands), this is done by the government at the owner’s expense.

As to excavations, in every case application to excavate must be made to the minister, who has a general supervision over the work and may stop it temporarily or assume the conduct of it. The state can excavate on private ground, but pays compensation; and can expropriate ground on which it wishes to excavate or on which discoveries have been made, the “archaeological value” not being reckoned. As to finds, if the state conducts the excavation, the owner retains one-fourth of the value of or the objects discovered at the choice of the state, the rest belongs to the state. In other cases, and in the case of chance discoveries (notice of which must be given immediately), the state takes one-half, but if the excavation is conducted by foreign institutions or persons, then the discoveries must be given to a public museum, or if part is handed over to the finder, it must be kept in such a way as to be accessible to the Italian public. The ministry gives periodical reports of all work carried out by the authorities in the Notizie degli Scavi and the Bollettino d’arte, both of which appear every month. The funds at the disposal of the ministry for purchases include (a) a sum of £40,000 already invested, (b) the interest upon £100,000 rentes regularly paid in, (c) other sums from sales of publications, fines, &c.; (d) an annual credit voted in the budget (£12,000 in 1909-1910), forming an account called the monete di belle arti.

The regulations issued in 1910 for the execution of the new law consist of some 200 articles in three divisions—one dealing with the artistic and historical patrimony of Italy and its internal administration, a second with the question of exportation, and the third with financial matters. (T. As.)

Greece.—The earliest regulations are those contained in the law of 1837, promulgated by royal decree. This has been replaced by the Monument Act of 1899, but the principles of the earlier law are retained; and the later act still lays down “the most extensive claim that any state has ever put forward in the matter of monuments,” viz. that “all objects of antiquity in Greece, as the productions of the ancestors of the Hellenic people, are regarded as the common national possession of all Hellenes.” The department in charge of the administration of the act is that of the minister of religion and public instruction. There is a central commission working with local commissions and a body of conservators. The control of this executive is in the hands of the ephor-general of antiquities. The act protects medieval monuments as well as those of classical Greece. All immovable monuments are public property, but compensation is to be paid to private owners if such monuments are to be preserved. Movable antiquities, if worthy of preservation by the state, must be placed in public museums. If discovered on private property the owner receives half the value, and may keep those not removed to a museum; all, however, must be registered. Excavations can be made anywhere by the state, and permission for private work must be first obtained. Expropriation is allowed. The export of antiquities is strictly forbidden under severe penalties, and the infringement of the various provisions of the act can be punished by heavy fines or imprisonment.

Austria-Hungary.—There is no legislation for the empire as a whole. In Austria there is a central commission, established 1850, whose authority is regulated by rescripts of 1873 and 1899 of the minister of religion and education. It consists of twenty members selected from experts in history, art and archaeology; there is also a numerous body of conservators who have districts covering the country assigned to them. They have no executive powers, but report on all new works likely to injure monuments, make inventories, influence public opinion, and work with archaeological societies for the general promotion of research and the safeguarding of ancient monuments. Hungary, on the other hand, has a Monument Act of 1881. With regard to any existing monument, the minister of religion and education decides whether it is worth preserving. Then the owner, whether public or private, must preserve it at his own cost. If that is impossible the minister may expropriate it. Compulsory purchase may also be resorted to for the purpose of preservation.

Belgium.—There is no monument legislation, but there is a royal commission, resembling that of Austria, founded in 1835, and a royal decree of 1842 prevents alienation of objects of interest contained in churches or alienation or reconstruction of churches without state permission. An inventory has been in progress since 1861, and the commission publishes a Bulletin. By a communal law of 1836 local administrations have to submit proposals for the destruction or repair of monuments to the committee of the provincial council, and must obtain royal approval. Expropriation on the ground of public utility may be resorted to for the protection of a threatened monument in the hands of a private owner.

Holland.—A state commission (Rijkscommissie) was established in 1903, and began an inventory of all monuments, movable and immovable. Any proposed alteration or demolition of buildings of interest in a town must be reported by the burgomaster to the minister of the interior. The annual budget of the minister of the interior contains sums to be allotted for the repair of specified monuments.

Switzerland.—Legislation is in the hands of the cantons; Vaud, Neuchâtel and Bern have passed Monuments Acts, modelled on that of France. The federal government may allot an annual grant for the acquisition and upkeep of national monuments and for excavations. There is a federal commission, established in 1886, whose functions, mainly those of other countries, are exercised by the Swiss Society for the Preservation of Monuments of Historical Art.

The preservation of scenery and of natural monuments is considered a matter of great importance, and in 1905 was founded a Swiss society which has a branch in the United Kingdom, La Ligue pour la conservation de la Suisse pittoresque et l’Heimatschutz. The special object of the society is the prevention of the defacement of Alpine scenery by funicular and other railways, mountain-lifts, power-stations, &c. It was successful in protecting the falls of the Rhine at Schaffhausen from a Zurich electric-power scheme.

Denmark.—The means adopted are an excellent example of what can be done without legislation by appeals made by a central authority working with expert knowledge to an enlightened public opinion and to national sentiment. The authority consists of an inspector of ancient monuments and the directorate of the Museum of Northern Antiquities at Copenhagen, exercising the functions of a royal commission that was established in 1807 and dissolved in 1840. The successful preservation of antiquities is also due to an old law, modified by royal decrees of 1737 and 1752, by which all finds of gold, silver and precious objects belong to the state, and to a declaration of 1848 that all monuments on the Crown domains are national property and are to be used only for the state’s own advantage. Many private owners have followed the example of the Crown. G. Baldwin Brown (op. cit. p. 188 seq.) gives some interesting examples of the success of the directorate of the museum in preserving monuments by appeals to ecclesiastical owners, projectors of railways and other works, and companies engaged in reclaiming land.

Sweden.—There is a state antiquary (Riksantikvare), appointed first by Gustavus Adolphus; the functions of a commission are exercised by the Royal Academy of Science, History and Antiquities, founded in 1786. There is an elaborate and stringent code of regulations protecting monuments, contained in royal decrees of 1867, 1873 and 1886. These are based on the edict of Charles XI. (1666), declaring all ancient monuments under royal protection. Sweden possesses one of the fullest inventories contained in the antiquarian topographical archives.

Norway.—Here there is also a state antiquary, and a state-subsidized society, Foreningen til norske Forfølgeres og middensamarkeres Fingrolle (founded in 1844, which acts much as a commission, and advises the state official.

Russia.—The care of ancient monuments is in the charge
of the ministry of the imperial court, of which the Imperial Archaeological Commission, founded in 1859, is a department. The Imperial Academy of the Fine Arts is joined in this charge with the commission, whose duties resemble in the main those of the commissions of other countries. By a circular of 1901 a complete inventory of the monuments of the country was ordered to be made by the local authorities.

Spain.—A monument commission was established in 1844; it works under regulations issued in 1865. It is composed of the Royal Academies of Fine Arts and of History, corresponding members of which form commissions for the provinces of the kingdom. A complete inventory of all monuments is being made. The minister in charge is that of public instruction and of the fine arts.

Portugal.—A decree of John V. (1721) protected the monuments of ancient times; in 1840 this protection was extended to medieval monuments. An inventory was begun in 1841. A council of national monuments was established in 1907 by a royal decree, with a code of regulations. The French system of classement is adopted, and the regulations under the French act of 1887 are generally followed. The minister responsible is that of public works, commerce and industry.

Turkey.—The regulations, as embodied in an irade of 1884, are very stringent, and the principle adopted is that of Greece, that all objects of antiquity belong to the state. The private owner of such has no power of disposition, and must not injure nor destroy them. All excavations are under the control of the government, and permission must be first obtained. The exportation of finds is forbidden, and all movable discoveries belong to the Imperial Museum. If these finds are the result of excavations, one-twentieth of the value goes to the discoverer; if of accidental discovery, the owner of the soil and the state divide.

The United States.—With regard to the remains of primitive man, earthworks, barrows, &c., some of those states, such as Ohio, which are specially rich in such monuments, have particular laws protecting individual remains, e.g. the earthworks in Warren county. The state exercises control over other remains of interest, e.g. the Eagle earthworks in Licking county. There is also an archaeological and historical society, partly maintained by the state, with the object of the better preservation of the evidences of the prehistoric occupation. In North Dakota a state historical commission was created in 1895 "to collect and preserve the records and relics pertaining to the early history, settlement and development of North Dakota."
The sites of the battle-fields, and statues, &c., erected in commemoration of the War of Independence or the Civil War, are preserved by various methods—by state or municipal regulation, by the action of incorporated bodies or trustees, &c. Most of the states rely on statutory prohibitions of malicious damage to protect their monuments and old buildings, &c.

MONVEL (1745-1812), French actor and dramatic writer, whose real name was Jacques Marie Boutet, was born in Lunéville on the 25th of March 1745. He was a small, thin man without good looks or voice, and yet he became one of the greatest comedians of his time. After some years of apprenticeship in the provinces, he made his début in 1770 at the Comédie Française in Mérope et Zenside; he was received sociétair on 1772. For some reason unknown Monvel secretly left Paris for Sweden about 1781, and became reader to the king, a post which he held for several years. At the Revolution he returned to Paris, embarking on a career of patriotic plays. When 70 he joined the theatre in the rue Richelieu (the rival of the Comédie Française), which, under Talma, with Dugazon, his sister Mme Vestris, Grandmesnil (1737-1816) and Mme Desgarcis, was soon to become the Théâtre de la République. After the Revolution Monvel returned to the reconstituted Comédie Française with all his old companions, but retired in 1807. Monvel was made a member of the Institute in 1795. He wrote six plays (four of them performed at the Comédie Française), two comedies, and fifteen comic operas, seven with music by N. Dezéde (1740-1792), eight by Nicolas d'Alayrac (1753-1800). He also published an historical novel, Frédégonde et Brunehaut (1776). He was professor of elocution at the Conservatoire. Monvel's two daughters, Milles Mars astrée and cadette, were well-known actresses.

MONZA (locally Monesia), a city of Lombardy, Italy, in the province of Milan, 8 m. by rail N.N.E. of that city, with which it is also connected by both steam and electric trams. It lies on the Lambro, a tributary of the Po, 532 ft. above sea-level. Pop. (1906), 32,000 (town); 53,330 (commune). Of the medieval fortifications little remains save the Porta d'Agrate. Near it is the nunnery in which the nun of Monza (see Manzoni's Promessi sposi) was enclosed. The cathedral of St John Baptist is the main object of interest; Theodolinda's basilica of 900 was enlarged at the close of the 13th century by throwing the atrium into the main building, and the present fine black-and-white marble façade was erected about the middle of the 14th by Matteo da Campione, and restored in 1809-1901. On the left-hand side of the front rises an incongruous brick-built tower, 278 ft. high, erected by Fellegreni in 1502-1506. Within the church are the iron crown of Lombardy, supposed to have been beaten out of one of the nails used at the Crucifixion, and the treasury containing the relics of Theodolinda, comprising her crown, fan and comb of gold, and the golden hen and seven chickens, representing Lombardy and her seven provinces, and crosses, reliquaries, &c., of the Lombard and Gothic periods. The interior has been modernized; there is a fine relief by Matteo da Campione in the organ-loft, representing the coronation of a king, and some 15th-century frescoes with scenes from the life of Theodolinda. Next to the cathedral in artistic importance come the church of Santa Maria in Strada, and the broletto or old palace of the commune, usually styled the Arengario; the former (founded in 1357) has a rich terra-cotta façade of 1566, and the latter is raised on a system of pointed arches and has a large square tower terminating in machicolations surrounding a sharp central cone. The royal palace of Monza (built in 1777 for the archduke Ferdinand) lies not far from the town on the banks of the Lambro. Cotton goods and felt hats are the staple products of the flourishing Monza industry; then dyeing, organ-building, and a publishing trade.

Monza (anc. Medicis) was not a place of consequence till it attracted the eye of Theodoric; and its first important associations are with Theodolinda. During the period of the republics Monza was sometimes independent, sometimes subject to Milan. The Visconti, who ultimately became masters of the city, built a castle in 1325 on the site now occupied by the Palazzo Durini. In the course of its history Monza stood thirty-two sieges, and was repeatedly threatened especially by the forces of Charles V. The countship (1499-1796) was purchased in 1570 by a wealthy banker Durini, and remained in his family till the Revolution. At Monza King Humbert was assassinated on the 29th of July 1900.

MONZONITE, the group-name of a type of rocks which have acquired it from their most celebrated occurrence, that of Monzoni in Tirol. The rocks are of granitic appearance, usually rather dark grey in colour and fine to moderately coarse grained. The special characteristic which distinguishes them from granites and ordinary syenites is the presence of plagioclase and orthoclase felspars in nearly equal amounts. Labradorite, andesine and oligoclase are present, usually in well-shaped crystals, often zoned; orthoclase forms large irregular plates in which the other minerals are embedded. There is rarely any porphyritic development, though in few of the rocks the quartz in this mineral occurs (the quartz-monzonites). Other features are the abundance of augite, pale green or brownish green, and of large bronze-coloured plates of biotite which are of quite irregular shapes and full of enclosures. Hypersthene or bronzite is less common, but dark brown and green hornblende are sometimes abundant. Olivine also may be present; when the rock contains this in notable quantity it may be called an olivine monzonite. Numerous large prisms of apatite often characterize micro-sections of monzonites, and zircon, iron ores and pyrites are frequent accessory minerals.
The monzonites of Tirol show a great variability in appearance, structure, and the relative proportions of their minerals. They tend to pass into rocks which have been called diabases and gabbros, and near the margins of the outcrop facies very rich in pyroxene (pyroxenites) occur. Many authors believe that this variety of types is associated with the fact that the monzonites occupy a middle place as regards their chemical composition between the acid and the basic igneous rocks, and that such a magma is naturally somewhat unstable, and likely to split up or differentiate into partial magmas of more siliceous and less siliceous character. The monzonites in fact approach rather closely to the calculated mean composition of the outer portion of the earth's crust and from a molten magma of this nature it is natural to suppose that all kinds of igneous rocks have been derived.

Rocks of monzonitic facies occur also in Norway, where they have been described as akérites. They contain quartz, orthoclase and plagioclase, augite and dark brown biotite; hornblende and hypersthene also may be present. Some of them have porphyritic rather than granitic texture, especially near the margins of the laccolites. From a study of these and other occurrences BLUGER proposed to define the monzonites as orthoclase-plagioclase rocks in which the two chief classes of felspar occur in nearly equal quantities (as distinguished from the orthoclase rocks or granites and the plagioclase rocks or diorites and anides of Norway).

At Yogo Peak and Beaver Creek in Montana, U.S.A., there are masses of granitoid rock which bear a close resemblance to the monzonites of Tirol. Two main types occur: (a) yogoite, which differs little from monzonite; and (b) shonkinite, which is a more basic rock rich in plagioclase and augite; this rock contains olivine and in places passes into dark pyroxenites. In shonkinite also a little nepheline may be present. In several places in the vicinity of Yogo Peak (Argyllshire) many masses are known which consist of an olivine-bearing rock closely related to monzonite, but has been called kentallenite because it is quarried at Kentallen in Argyllshire. Large crystals of pale green augite and irregular plates of biotite which enclose idiomorphic plagioclase felspar are common in micro-sections of this rock, and the abundance of olivine is rather greater than is usual in the monzonites; it is associated with diorites of lamprophyric character and dark pyroxenites and peridotites.

The following table shows the chemical peculiarities of the principal rocks of the monzonite group:

| SiO₂, Al₂O₃, Fe₂O₃, FeO, MgO, CaO, K₂O, Na₂O | 52.40, 15.73, 3.67, 5.40, 4.80, 5.42, 3.07 |
| Yogoite, Yogo Peak | 6.12, 61.28 |
| Kentallenite, Argyllshire | 52.09, 11.93, 4.81, 7.12, 14.87, 9.84, 1.24, 0.04 |

MOOD. (1) (O. Eng. mood, a word common to Teutonic languages; cf. Ger. Mut; Du. mood, mind, courage), a particular state of mind or feeling. (2) (Adapted from Lat. modus, measure), a grammatical term for one of the various forms into which the conjugation is grouped, showing whether the verb is used as a predicate, a wish, a command, &c. In systematic logic the term is used of the various classes into which the "figures" of valid syllogisms are divided. (See SYLLOGISM.)

MOODKE, or MUKDI, a town in the Ferza-pore district of the Punjab, India. Pop. (1901), 29,177. It is situated 26 m. S. of the Sutlej, on the old road from Ferza-pore to Karnal, and is notable as the scene of the first battle (Dec. 18, 1845) in the first Sikh war. (See Sikh Wars.)

MOODY, DWIGHT LYMAN (Ryther) (1837-1890), American evangelist, was born in the village of East Northfield (Northfield township), Massachusetts, on the 5th of February 1837. His father died in 1841, and young Dwight, a mischief-loving independent boy, got a scanty schooling. In 1854 he became a salesman in a shoe-store in Boston; in 1855 he was "converted"; and in 1856 he went to Chicago and started business there. Beginning with a class gathered from the streets, he opened (1858) a Sunday school in North Market Hall, which was organized in 1863 as the Illinois Street Church, and afterwards became the Chicago Avenue Church, of which he was pastor. In 1866 he gave up business and devoted himself to missionary work. He was prominent in raising money for Farwell Hall in Chicago (1867), and in 1863-1865 was president of the Chicago Young Men's Christian Association. Ira David Sankey (1840-1908) joined him in Chicago in 1870 and helped him greatly by the singing of hymns; and in a series of notable revival meetings in England (1873-1875, 1881-1884, 1891-1892) and America they carried on their gospel campaign, and became famous for the "Moody and Sankey Gospel Hymns." In 1879 Moody opened the Northfield seminary for young women, at Northfield, Mass., and in 1881 the adjacent Mount Hermon school for boys; in each a liberal practical education centres about Bible training; the boys do farm-work and the girls house-work. In 1889 he opened in Chicago the Bible Institute, and there trained Christian workers in Bible study and in practical methods of social reform; at Northfield in 1890 he opened a Training School in domestic science in the Northfield Hotel, formerly used only in summer for visitors at the annual conferences, of which the best known are the Bible (or Christian Workers') Conference, first held at Northfield in 1880, and the Students' (or College-Men's) Conference, first held in 1887.

Moody died at Northfield on the 22nd of December 1899. His sermons were colloquial, simple, full of conviction and point. In his theology he laid stress on the Gospel and on no sectarian opinions—he was, however, a pre-millenarian—and he worked with men as much more "advanced" than himself as Henry Drummond, whom he eagerly defended against orthodox attack, and George Adam Smith. Moody's sermons were sold widely in English, and in German, Danish and Swedish versions.

MOOLVIE (an Urdi variant of Arabic mulawī, a derivative of mulūk, a man learned in the law), the name used in India of a man learned in Mahomedan law, and hence used generally of a teacher or as a complimentary title of one learned in any branch of knowledge.

MOON, SIR RICHARD, 1ST BARONET (1814-1899), English railway administrator, was the son of a Liverpool merchant, and was born on the 23rd of September 1814. The history of his life is practically the history of the London & North Western railway for the period in which he lived. When he first became a member of the board in 1847, the company had just come into existence by the amalgamation of the London & Birmingham, the Manchester & Birmingham, and the Grand Junction lines, and it was during his long connexion with it—first as director and then (from 1862 to 1891) as chairman—that its system was developed substantially into what it is now. The Chester & Holyhead, the Lancaster & Carlisle, and many smaller lines were gradually added to it, either by leasing or by complete absorption, and finally in 1877 an act was obtained consolidating all into one homogeneous whole. Throughout his career, Sir Richard Moon's powers of organization and his genius for what may be called railway diplomacy were of the greatest advantage to the company, and to him it owed in very large measure its commanding position. An extremely hard worker himself, he expected equal diligence of his subordinates; but energy and capacity did not go unrewarded, for he made promotions, not by standing in seniority, but by merit. Sir Richard Moon, who was created a baronet in 1887, died at Coventry on the 17th of November 1899.

MOON (a common Teutonic word, cf. Ger. Mond, Du. maan, Dan. maane, &c., and cognate with such Indo-Germanic forms as Gr. mënés, Sans. māsa, Irish ma, &c.; Lat. uses luna, i.e. lucna, the shining one, lucere, to shine, for the moon, but preserves the word in mensis, month; the ultimate root for "moon" and "month" is usually taken to be me- to measure, the moon being a measurer of time), in astronomy, the name given to the satellite of any planet, specifically to the only satellite of the earth.

The subject of the moon may be treated as twofold, one branch being concerned with the aspects, phases and constitution of the moon; the other with the mathematical theory of its motion. As the varying phenomena presented by the moon grow out of its orbital motion, the general character of the latter will be set forth in advance.

A luminous idea of the geometrical relations of the moon,
The Sun

The diagram shows the Sun, Earth, and Moon in their positions during the solar eclipse of 1866. The nodes N1 and N2 are marked, and the line NN' represents the direction of the nodes. The figure illustrates the movement of the Moon's nodes and the Earth's position during the eclipse.

The text discusses the relative positions of the Sun, Earth, and Moon during an eclipse, explaining the alignment of the Earth's shadow on the Moon and the apparent size of the Moon's shadow. It elaborates on the significance of the eclipse and the impact on solar activity.

In the context of the eclipse of 1866, the text provides a detailed account of the event, highlighting the scientific significance and the role of eclipse observation in understanding solar phenomena. It emphasizes the importance of such observations in mapping the solar system's dynamics and contributing to the development of astronomical theories.
feature of the surface comprises the craters, which are scattered everywhere, and generally surrounded by an approximately circular elevated ring. Yet another remarkable feature comprises bright streaks, branching out in various directions and through long distances from a few central points, especially that known before Tycho.

The height of the lunar mountains is a subject of interest. It cannot be stated with the same definitiveness that we can assign heights to our terrestrial mountains, because there is no fixed sea-level on the moon to which elevations can be referred. The only determination that can be made on the moon is that of the height above some neighbouring hollow, crater or plain. The most detailed measures of this sort were made by Beer and Mädler, who give a great number of such heights. These generally range between 300 and 3000 toises, or 3000 and 20,000 English feet. The highest which they measured was Newton, 3727 toises, or 24,000 ft.

The general trend of lunar investigation has been against the view that there is any resemblance between the surfaces of the moon and of the earth, except in the general features already noticed. No evidence has yet been found that the moon has either water or air. The former, if it existed at all, could be found only in the more depressed portions; and even here it would evaporate under the influence of the sun's rapid warming of the earth's surface. The most delicate indication of an atmosphere would be the refraction of the light of a star when seen coincident with the limb of the moon. Not the slightest change in the position of such a star when in this position has ever been detected, and it is certain that if any occurs it can be but a minute fraction of a second of arc. As an atmosphere equal to ours in density would produce a deviation of an important fraction of a degree, it may be said that the moon can have no atmosphere exceeding in density the 1,57056 of that of the earth.

Devoid of air and atmosphere, the causes of meteorological phenomena on the earth are non-existent on the moon. The only active cause of such changes is the varying temperature produced by the presence or absence of the sun's rays. The range of temperature must be vastly wider than on the earth, owing to the absence of an atmosphere to make it equitable. Elaborate observations of the heat coming from the moon at different phases have been made and discussed in 1871-1872 by Lord Rosse. Among his results was that during the progression of the moon from its first to the full moon the heat received increases in a much greater proportion than the light, from which it followed that the former was composed mainly of heat radiated from the moon itself in consequence of the temperature which it assumes under the sun's rays. So far as could be determined, 86% of the heat radiated was by the moon itself, and 14% reflected solar heat. But it seems probable that this disproportion may be somewhat too great. Rosse's determinations, like those of his predecessors, were made with the thermopile. After S. P. Langley devised his bolometer, which was a much more sensitive instrument than the thermopile, he, in conjunction with F. W. Very, applied it to determine the moon's radiation at the Allegheny observatory. His results for the ratio of the total radiation of the full moon to that of the sun ranged from 1:70,000 to 1:110,000, which were in substantial agreement with those of Rosse, who found 1:82,000. When Langley published his work the law of radiation as a function of the temperature was not yet established. He therefore wrongly concluded that the highest temperature reached by the moon approximated to the boiling-point of water. Stefan's law of radiation, on the other hand, shows that the temperature must have been about the boiling-point in order that the observed amount of heat might be radiated. This is in fair agreement with the computed temperature due to the sun's radiation upon a perpendicular absorbing surface when no temperature is lost through conduction to the interior. The agreement thus brought about between the results deduced from the law of radiation and the most delicate observa-

- **MOON**

- **Possibility of Changes on the Moon.**—No evidence of life on the moon has ever been brought out by the minutest telescopic scrutiny, nor does life seem possible in the absence of air and water. Some bright spots are visible by the earth-light when the moon is a thin crescent, which were supposed by Herschel to be volcanoes in eruption. But these are now known to be nothing more than spots of unusual whiteness, and if any active volcano exists it is yet to be discovered. Still, the question whether everything on the moon's surface is absolutely unchangeable is as yet an open one, with the general trend of opinion toward the affirmative, so far as any actual proof from observation is concerned. The spot which has most frequently exhibited changes in appearance is near the centre of the visible disk, marked on Beer and Mädler's map as Lune. This has been found to present an aspect quite different from that depicted on the map, and one which varies at different times. But the question still remains open whether these variations may not be due wholly to the different phases of illumination by the sun's rays. The question of the moon's temperature and internal heat is one of the points in which the moon is most different from the earth, and the question concerning the origin of the moon is the ratio of moonlight to sunlight. This has been measured for the full moon by various investigators, but the results are not as accurate as could be desired. The most reliable determinations were made by G. P. Bond at Harvard and F. Zöllner at Leipzig, in 1860 and 1864. The mean result of these two determinations is the ratio 1:570,000. We may therefore say that the intensity of sunlight is somewhat more than half a million times that of full moonlight. A remarkable feature of the reflecting power of the moon, which was made known by Zöllner's observations, is that the proportion of light reflected by a region on the moon is much greater when the light falls perpendicularly, which is the case near the time of full moon, and rapidly becomes less as the light is more oblique. This result was traced by Zöllner to the general irregularity of the lunar surface, and the inference was drawn that the average slope of the lunar elevation amounts to 47°.

- **Motion of the Moon.**—The orbit of the moon around the earth, though not a fixed curve of any class, is elliptical in form, and may be represented by an ellipse which maintains its form and position, and has the earth in one of its foci. The eccentricity of the ellipse is in the general average about 0.055, whence the moon is commonly more than 3/7 further from the earth at apogee than at perigee. The line of apsides is in continual motion, generally direct, and performs a revolution in about 7 years. The inclination to the ecliptic is a little more than 5°, and the line of nodes performs a revolution in the retrograde direction in 18.6 years. The parallax of the moon is determined by observation from two widely separated points; the most accurate measures are those made at Greenwich and at the Cape of Good Hope. The distance of the moon can also be computed from the law of gravity, the problem being to determine the distance at which a body having the moon's mass would revolve around the earth in the observed period. The measures of parallax agree perfectly with the computed distance in showing a mean parallax of 37.2°, and a mean distance of 238,800 miles. The period of revolution, or the lunar month, depends upon the point to which the revolution is referred. On our own fixed stars, the time of revolution for those chosen that of the sun, the fixed stars, the equinox, the perigee, or the node. The terms synodical, sidereal, tropical, anomalistic, nodal, are applied respectively to these months, of which the lengths are as follow—

The Mathematical Theory of the Moon.

The mathematical theory of the moon’s motion does not yet form a well-defined body of reasoning and doctrine, like other branches of mathematical science, but consists of a series of researches, extending through twenty centuries or more, and not easily welded into a unified whole. Before Newton the problem was that of devising empirical curves to formally represent the observed inequalities in the motion of the moon around the earth. After the establishment of universal gravitation and the discovery of the three branches of the moon’s motion, the problem was reduced to that of integrating the differential equations of the moon’s motion, and testing the completeness of the results by comparison with observation. Although the precision of the mathematical solution has been placed beyond serious doubt, the problem of completely reconciling this solution with the observed motions of the moon is not yet completely solved.

Under these circumstances the historical treatment is that best adopted to give a clear idea of the progress and results of research in this field. Modern researches were developed so naturally from the results of the ancients that we shall begin with a brief mention of the work of the latter.

It is in the investigation of the moon’s motion that the merits of the ancient astronomy are seen to the best advantage. In the hands of a great man, astronomy was an ingenious, and at times a profound, science which is really marvellous when we compare it either with other branches of physical science in that age or with the views of contemporary non-scientific writers. The discoveries of Hipparchus were so many that he has been called the first to study them. He found that the moon moved most rapidly near a certain point of its orbit, and most slowly near the opposite point. The law of this motion was such that the phenomena could be represented by supposing the motion to be actually along the curved line forming the path of the moon, but the hypothesis was not at all correct. In most cases, the true path diverges from the supposed path, the discrepancy being explained by the hypothesis that the earth was not situated in the centre of the orbit, but was displaced by an amount equal to one-twentieth of the radius of the orbit. Thus, by an obvious law of physics, the moon’s motion was such that the moon would be at a point nearest the earth, that is at perigee, and slowest at the point most distant from the earth, that is at apogee. Thus the apogee and perigee became two definite points of the orbit, indicated by the Greek symbols ω (omega) and α (alpha).

These points are at the ends of that diameter of the orbit which passes through the eccentrically situated earth, or, in other words, they are on that line which passes through the centre of the earth and the centre of the orbit. This line was called the line of apsidal points. On comparing observations made at different times it was found that the line of apsides was not fixed, but made a complete revolution in the heavens, in the order of the signs of the zodiac, in about nine years.

1. The Mathematical Theory of the Moon’s Motion.

The mathematical theory of the moon’s motion was also developed in the second century B.C. by Eudoxus of Knidos. He supposed that the moon moved in an oval orbit about the earth, and that the earth moved in a circular orbit about the sun. The moon was supposed to move in a circle about the earth, and the earth moved in a circle about the sun. By taking three eclipses separated at short intervals, both the moon’s motion and the perigee would be known beforehand, from other data, with sufficient accuracy to reduce the number of unknown quantities. The moon’s motion and the perigee were determined in this way, and then the only three elements already mentioned remained unknown. The same three elements being again determined from a second triplet of eclipses at as remote an epoch as possible, the difference in the longitude of the perigee at the two epochs gave the annual motion of that element, and the difference of mean longitudes gave the mean motion.

The eccentrics of the moon were determined in this way with a degree of accuracy that was much greater than the degree of accuracy in the observations. The result of the latter inequality was brought out when he sought to determine the eccentricity of the orbit from the observations near the time of the first and last quarter. It was thus found that the moon’s orbit was an ellipse, which is now known as the ejection. The relations of the quantities involved may be shown by simple trigonometrical formulae. If we put g for the moon’s anomaly or distance from the perigee, and D for its elongation from the sun, the inequalities in question as now known are:

- 6.29 g sin 1+27° sin (2D-g) (equation of centre)
- 6.29 g sin 27° sin g = 5.02° sin g

Therefore the eccentricity found by Hipparchus was only 5°, and was more than a degree less than its true value. At first quarter and last quarter, when D = 90°, we find that the value of 2D in the last term of the above equation, we see that the combined equation of the centre and the ejection are, at quadrature:

- 6.29 g sin 41.27° sin g = 7.56° sin g

Thus, in consequence of the ejection, the equation of the centre comes out 27° 50’ nearer from observations at the moon’s quarters than from observations at the full moon.

The next forward step was due to Tycho Brahe. He found that, although the two inequalities found by Hipparchus and Ptolemy correctly represented the moon’s longitude near conjunction and opposition, they did not apply at all to the moon’s motion at the most asymmetrical points. Many of the observations have been found that when the moon was 45° or 135° on either side of the sun, the observed motion was very different from what had been supposed, on the part of the Arabians, any such exact description of the orbit as necessary to make clear his claim to the discovery. We may conclude the ancient history of the lunar theory by saying that the only real revolution by expressing the time in terms of the moon’s true longitude. Then, by inverting the series, the longitude was expressed in terms of the time.

2. The Numerical Determination of the Elements of the Moon’s Motion.

In order to prove that the two capital discoveries just mentioned should have the highest scientific value, it was essential that the numerical values of the elements involved in these differential equations of motion be fixed with precision. This Hipparchus was enabled to do by lunar eclipses. Each eclipse gave a moment at which the longitude of the moon was 180° different from that of the sun. The latter admitted of ready calculation. Assuming the earth to be precisely at the same distance from the sun as the moon was, three eclipses, observed in different points of the orbit, would give as many true longitudes of the moon, which longitudes could be employed to determine three unknown quantities—the mean longitude of a given epoch, the eccentricity, and the position of the perigee. By taking three eclipses separated at short intervals, both the moon’s motion and the perigee would be known beforehand, from other data, with sufficient accuracy to reduce the number of unknown quantities. The moon’s motion and the perigee were determined in this way, and then the only three elements already mentioned remained unknown. The same three elements being again determined from a second triplet of eclipses at as remote an epoch as possible, the difference in the

determination of the numerical quantities required. It has the disadvantage of giving the solution of the problem only for a particular case, and of being inapplicable in researches in which the general equations of dynamics have to be applied. It has been employed by Danoiseau, Hansen and Airy.

The methods of the second general class are those most worthy of study. Among these we must assign the first rank to the method of C. É. Delaunay, developed in his *Théorie du mouvement de la lune* (2 vols., 1860, 1867), because it contains a germ which may yet be regarded as the grand desideratum of a general theory of celestial mechanics.

Among applications of the third or numerical method, the most successful yet completed is that of P. A. Hansen. His first work, *Principia nova*, appeared in 1853. The tables contain an expansion of his ingenious and peculiar methods of computation. During the twenty years following he devoted a large part of his energies to the numerical computation of the lunar inequalities, the determination of elements of motion, and the preparation of the tables for computing the moon’s position. In the latter branch of the work he received material aid from the British government, which published his tables on their completion in 1857. The work was published over some seven years later by the Royal Society of Sciences.

It was found on comparing the results of Hansen and Delaunay that there are some outstanding discrepancies which are of such magnitude as to demand another examination of the mathematical theory of the subject. It was therefore necessary that the numerical inequalities should be again determined by an entirely different method.

This has been done by Ernest W. Brown, whose work may be regarded not only as the last word on the subject, but as embodying a completely satisfactory solution of a problem which has absorbed an important part of the energies of mathematicians and astronomers for the last quarter century. The solution is given in a year-by-year account of the position of the moon by the two methods, and it is thus possible to convey an idea of the solution. We have just mentioned the four small quantities $e_1$, $e_2$, $\gamma$, and $m$, in terms of the powers and products of the moon’s co-ordinates to be expressed. Euler considered these sums as standing on a preliminary problem in which the orbits of the planets would be supposed to lie in the ecliptic, and to have no eccentricity, while that of the sun was circular. This solution being reached, the additional terms were found, which were multiplied by the first power of the several eccentricities, and the result expressed in terms of the mean order were found, and so on to any extent. In a series of remarkable papers published in 1877–1888 Hill improved Euler’s method, and worked it out with much more rigour and fullness than Euler had been able to do. The vast contribution of Hill has consisted in working out by extremely elegant mathematical processes the method of determining the motion of the planets. John Couch Adams afterwards determined the motion of the planet Mercury from the perturbations produced in the great planet by Hill’s method so as to form a practically complete solution of the entire problem. The principal feature of his work was that he found the quantity $m$, which is regarded as constant, appears only in a numerical factor. Thus the analysis unites the equal development in a series accruing to its powers is done away with.

The motion of the moon is mathematically correct thus reached is that of the motion of three bodies only—the sun, earth, and moon. The moon of course is the earth then invariable, the longitude containing no inequalities of longer period than that of the moon’s node, 18-6 y. But Edmund Halley found, by a comparison of ancient eclipses with modern observations, that the mean motion of the moon had been accelerated. This acceleration is determined by Richard Doppler and Airy. The first step in this process was to observe the acceleration, and the inference that it is an effect of the planets in some way influence the moon’s motion. Thus a new branch of the lunar theory was suggested—the determination of the theory by the effect of the planets on the moon.

The first step in constructing this theory was taken by Laplace, who showed that the secular acceleration was produced by the secular diminution of the earth’s orbit. He computed the amount as would be necessary to the results derived by Dunthorne from ancient eclipses. Laplace’s immediate successors, among whom were Hansen, Plana and Pontécoulant, found a larger value, Hansen increasing it to 12-5, which he introduced by his law. The value was found still more accurately by Dunthorne and Airy to represent fairly well several ancient eclipses of the sun, notably the supposed one of Thales. But Adams in 1853 showed that the previous computations of the acceleration were only a rude first approach, and that more accurate results could be obtained by an analysis of the observations to within one-half. This diminution was soon fully confirmed by others, especially Delaunay, although for some time Pontécoulant stoutly maintained the correctness of the older result. But the demonstration of Adam’s result was soon made conclusive, and a value which may be regarded as definite has been derived by Brown. With the latest accepted diminution of the eccentricity, the coefficient is 5-91.

The question now arose of the origin of the discrepancy between the theory and the observation. The question was answered by observations of sun spots made from ancient eclipses. In 1856 William Ferrel showed that the action of the moon on the ocean tides would result in a retardation of the earth’s rotation, a result, at first unnoticed, which was independently reached by Anker. Ferrel assumed that this retardation does not admit of accurate computation, owing to the uncertainty both as to the amount of the oceanic friction from which it arises and of the exact height and form of the tidal wave, the action of the moon on which produces the effect. But any rough estimate can be made shows that it might well be supposed much larger than is necessary to produce the observed differences of 6° per century. It was therefore surprising when, in 1877, Simon Newcomb found, by a study of the lunar eclipses handed down by Ptolemy and those observed by the ancient astronomers, that the actual apparent acceleration was only about 8.3°. This is 2-4° larger than the theoretical value, and it seems difficult to suppose that the effect of the tidal retardation can be as small as this. This suggests that the retardation may be in great part compensated by some accelerating cause, the existence of which is not yet well established. The following is a summary of the present state of the question.

The theoretical value of the acceleration, assuming the day to be constant, is

| Hansen’s value in his *Tables de la lune* | 12-19 |
| Hansen’s revised, but still theoretically erroneous, result | 12-56 |
| The value which best represents the supposed eclipses | 11-7 |

The result of purely astronomical observation is

**Inequalities of Long Period.**—Combined with the question of secular acceleration is another which is still not entirely settled—that of inequalities of long period in the mean motion of the moon round the earth. Laplace first showed that modern observations of the moon indicated that its mean motion was really less during the last half of the 19th century than in earlier times and hence inferred the existence of an inequality having a period of more than a century.

The existence of one or more such inequalities has been fully contemplated by all astronomers, but partly and recently, that have become available since the time of Laplace. It is also found by computation from theory that the planets do produce several appreciable inequalities of long period, as well as a great number of short periods in the motion of the moon. The former do not correspond to the observed inequalities, and the explanation of the outstanding differences may be regarded to-day as the most perplexing enigma in astronomy. The most plausible explanation of the inequalities in the secular acceleration as observed deviation is only apparent, and arises from slow fluctuations in the earth’s rotation, and therefore in our measure of time produced by the motion of the moon around the earth. The discovery of this case a similar inequality should be found in the observed times of the transits of Mercury. But the latter do not certainly show any deviation in the measure of time, and seem to preclude a deviation such. This suggests that inequalities in the action of the planets may have been still overlooked, the subject being the most intricate with which celestial mechanics has to deal. But this action has been recently worked up with such completeness and accuracy by Radu, Newcomb and Bessel, that the probability of a new discovery seems out of the question. The enigma therefore still defies solution.

MOONSEED—MOORE, A. J.

MOONSEED, in botany, a common name for Menispernum, a genus of climbing deciduous shrubs, containing one species in North America and another in Eastern Asia. The former, *M. caudense*, is a handsome plant, with lanky and weak stems, with large remiform peltate leaves and yellowish flowers borne in profusion on long pendulous racemes.

MOONSTONE, a variety of felspar, showing in certain directions a bluish opalescence, whence its value as an ornamental stone. When cut with a convex surface it displays a soft milky reflection, forming a luminous band, but not sharply defined as in cat's-eye. The ordinary moonstone is a translucent variety of orthoclase known as adularia (see ORTHOCLASIS), whence the peculiar sheen has been called "adularescence." The effect is probably caused by interference from twin lamellae, or by numerous enclosures of microscopic laminae, definitely orientated, and it has been suggested that these may often be flakes of kaolin, due to incipient decomposition of the felspar. Practically all the moonstone of commerce comes from Ceylon, principally from the Dumbarra district of the Central Province. It occurs as pebbles and irregular masses in the gem-gravels and clay-deposits, and is also obtained by quarrying an adularia leptinite, as described by A. D. K. Coomaraswamy. Very similar in some respects to moonstone is the chatoyant soda-felspar which was called by T. Serry Hunt peristerite, from Gr. περίστερα, a dove, in allusion to the resemblance of its lustre to that of the bird's neck. The original peristerite was from Bathurst, near Perth, Lanark county, Ontario, but it occurs also at Macomb, St Lawrence county, New York.

MOONWORT, or MOON-TERN, in botany, the popular name of a small fern (*Botrychium Lunaria*), belonging to the order Ophioglossaceae (see FERNS). It has a tuberous root-stock and a stout fleshy glabrous frond 3 to 6 in. long, with a sterile and fertile portion; the former bears several pairs of close-set, semi-circular or moon-shaped pinnae, the latter is pinnately branched and covered, on the face opposed to the sterile portion, with small globose spore-cases which burst transversely. It is a widely distributed plant in the north and south temperate and cold zones, and is found in pastures and grassy banks in Britain.

MOOR. (1) A body of water, an unenclosed stretch of waste or uncultivated land, covered with heather; also such a heath preserved for game-shooting, particularly for the shooting of grouse. The E. Eng. mór, bog, moor, is represented in other Teutonic languages; cf. Dan. mor, Ger. Moor, O. Du. moer, &c., from an O. Du. adjectival form mørach comes Eng. morass, O. Du. moer; Probably mere, marsh, are not to be connected with these words. (2) The verb "to moor," to fasten a ship or boat to the shore, to another vessel, or to an anchor or buoy, by cables, &c., is probably from the root seen in mod. Du. meren, which also gives the English nautical term "marline," small strands of rope used for lashings or seizings, and "marline-spike," a small iron tool for separating the strands of rope, &c.

MOORCROFT, WILLIAM (c. 1770–1829), English traveller, was born in Lancashire, about 1770. He was educated as a surgeon in Liverpool; but on completing his course he resolved to devote himself to veterinary surgery, and, after studying the subject in France, began practice in London. In 1795 he published a pamphlet of directions for the medical treatment of horses, with special reference to India, and in 1800 a Cursory Account of the Methods of Shoewing Horses. Having been offered by the East India Company the inspectorship of their Bengal stud, Moorcroft left England for India in 1808. Under his care the stud rapidly improved; in order to perfect the breed he resolved to undertake a journey into Central Asia to obtain a stock of Turkoman horses. In company with Captain William Hearsey, and encumbered with a stock of merchandise for the purpose of establishing trade relations between India and Central Asia, Moorcroft left Josimath, well within the mountains, on the 26th of May 1812. Proceeding along the valley of the Dauli, they reached the summit of the frontier pass of Niti on the 1st of July. Descending by the towns of Darba and Gartok, Moorcroft struck the main upper branch of the Indus near its source, and on the 5th of August arrived at the sacred lake of Manasarowar. Returning by Bhutan, he was detained some time by the Ghurkas, and reached Calcutta in November. This journey only served to whet Moorcroft's appetite for more travel, for while on his second journey he explored the eastern and western extensities of the Himalayas. In company with him and George Trebeck, Moorcroft set out on his second journey in October 1819. On the 14th of August the source of the Beas (Hyphasis) was discovered, and subsequently that of the Chenab. The capital of Lahad, which was discovered, was reached on the 24th of September, and here several months were spent in exploring the surrounding country. A commercial treaty was concluded with the government of Lahad, by which the whole of Central Asia was virtually opened to British trade. Kashmir was reached on the 3rd of November 1821, Jalalabad on the 4th of June 1824, Kabul on the 20th of June, and Bokhara on the 25th of February 1825. At Andkhi, in Afghan Turkestan, Moorcroft was seized with fever, of which he died on the 27th of August 1825. Trebeck surviving him only a few days. But according to the Abbé Huc, Moorcroft reached Lhasa in 1826, and lived there twelve years, being assassinated on his way back to India in 1838. In 1841 Moorcroft's papers were published by the Asiatic Society, and published, under the editorship of H. H. Wilson, under the title of Travels in the Himalayan Provinces of Hindustan and the Punjab, in Lahad and Kashmir, in Fashawur, Kabul, Kunduz and Bokhara, from 1819 to 1825. See Graham Sandberg, The Exploration of Tibet (1904).

MOORE, ALBERT JOSEPH (1841–1893), English decorative painter, was born at York on the 4th of September 1841. He was the youngest of the fourteen children of the artist, William Moore, of York who in the first half of the 19th century enjoyed a considerable reputation in the North of England as a painter of portraits and landscape. In his childhood Albert Moore showed
an extraordinary love of art, and as he was encouraged in his tastes by his father and brothers, two of whom, afterward became famous as artists—John Collingham Moore, and Henry Moore, R.A.—he was able to begin the active exercise of his profession at an unusually early age. His first exhibited works were two drawings which he sent to the Royal Academy in 1857. A year later he became a student in the Royal Academy schools; but after working in them for a few months only he decided that he would be more profitably occupied in independent practice. During the period that extended from 1858 to 1870, though he produced and exhibited many pictures and drawings, he gave up much of his time to decorative work of various kinds, and painted, in 1863, a series of wall decorations at Coome Abbey, the seat of the earl of Craven; in 1865 and 1866 some elaborate compositions: "The Last Supper" and "The Feeding of the Five Thousand" on the church walls of the church of St Alban's, Rochdale; and in 1868 "A Greek Play," an important panel in tempera for the procession of the Queen's Theatre in Long Acre. His first large canvas, "Elijah's Sacrifice," was completed during a stay of some five months which he spent in Rome at the beginning of 1867, and appeared at the Academy in 1868. A still larger picture, "The Shunamite, relating the Glories of King Solomon to her Maidens," was exhibited in 1866, and with it two smaller works, "Apricots" and "Pomegranates." In these Albert Moore asserted plainly the particular technical conviction which for the rest of his life governed the whole of his practice, and with them he first took his place definitely among the most original of British painters. Of his subsequent works the most notable are "The Quartette" (1869), "Sea Gulls" (1871), "Follow-my-Leader" (1873), "Shells" (1874), "Topaz" (1875), "Rose Leaves" (1880), "Yellow Marguerites" (1881), "Blossoms" (1881), "Dreamers" (1882), "Reading Aloud" (1884), "Silver" (1885), "Midsummer" (1887), "A River Side" (1888), "A Summer Night" (1890), "Lightning and Light" (1892), "An Idyll" (1893), and "The Loves of the Winds and the Seasons," a large picture which was finished only a few days before his death. He died on the 25th of September 1893, at his studio in Sussex Street, Westminster. Several of his pictures are now in public collections; among the chief are "Blossoms," in the National Gallery of British Art; "A Summer Night" in the Liverpool Corporation Gallery; "Dreamers" in the Birmingham Corporation Gallery; and a water-colour, "The Open Book," in the Victoria and Albert Museum, South Kensington. In all his pictures, save two or three produced in his later boyhood, he avoided any approach to story-telling, and occupied himself exclusively with decorative arrangements of lines and colour masses. The spirit of his art is essentially classic, and his work shows plainly that he was deeply influenced by study of antique sculpture; but he was not in any sense an archaeological painter, nor did he attempt reconstructions of the life of past centuries. Artistically he lived in a world of his own creation, a place peopled with robust types of humanity of Greek mould, and gay with bright-coloured draperies and brilliant-hued flowers. As an executant he was careful and certain; he had his eye on his picture, and aimed at its development and subtle appreciation. Few men have equalled him as a painter of draperies, and still fewer have approached his ability in the application of decorative principles to pictorial art.

MOORE, EDWARD (1712-1757), English dramatist and miscellaneous writer, the son of a dissenting minister, was born at Abingdon, Berkshire, on the 22nd of March 1712. He was the author of the domestic tragedy of The Gamester, originally produced in 1753 with Garrick in the leading character of Beverley the gambler. As a poet he produced clever imitations of Gay and Gray, and with the assistance of George, 1st Lord Lyttelton, Lord Chesterfield and Horace Walpole, conducted The World (1753-1757), a weekly periodical on the model of the Rambler. Moore collected his poems under the title of Poems, Fables and Plays in 1756. He died in Lambeth on the 1st of March 1757. His Dramatic Works were published in 1788.

MOORE, GEORGE (1853— ), Irish novelist and poet, was born in Ireland, son of George Henry Moore, M.P., a well-known tilerator and politician. He studied art in London and finished his education in Paris. He was a regular contributor to various London magazines when he published his first volume, in verse, The Flowers of Passion (1877). A second, Pagan, Poems, appeared in 1881. As a novelist he followed the French school of Flaubert and Zola, and became prominent for deliberate realism. His powerful Mummer's Wife (1885) has decidedly repulsive elements. But Zolaism meanwhile was a thing to which the reading public was gradually becoming acclimatized. George Moore's Esther Waters (1894), a strong story with an anti-gambling motive, had a more general success, and was followed by Evelyn Innes (1888), a novel of musical life, and its sequel, Sister Teresa (1901). He interested himself in the Irish Gaelic revival, and was one of the founders of the Irish Literary Theatre. His play, The Strike at Artingford (three acts, in prose, 1893), was written for the Independent Theatre, and his satirical comedy, The Bending of the Bough (1900), dealing with Irish local affairs, was played by the Irish Literary Theatre in Dublin. His Diamirud and Grania, written with Mr. W. B. Yeats, were produced by Mr. P. R. Benson's company at the same theatre in 1901. The Untitled Field (1903) and The Lake (1905) are romantic pictures of Irish life. Moore had originally come to the front in London about 1888 as an art critic, and his published work in that line includes Impressions and Opinions (1891) and Modern Painting (1893, 2nd ed., 1897). Among his other books are A Drama in Muslin, (1886), A Mere Accident (1887), Parnall and His Island (1887), Mike Fletcher (1887), Spring Days (1888), Vain Fortune (1890), Celibates (1892), Confessions of a Young Man (1888), and Memoirs of My Dead Life (1906).

MOORE, GEORGE FOOT (1837- ), American Biblical scholar, was born in West Chester, Pennsylvania, on the 15th of October 1851, the son of William Eves Moore (1823-1899), a prominent Presbyterian minister, long the permanent clerk of the Presbyterian General Assembly. The son graduated at Yale in 1872 and at Union Theological Seminary in 1877, was ordained in the ministry in 1878, and from 1878 to 1883 was pastor of the Putnam Presbyterian Church, Zanesville, Ohio. He was Hitchcock professor of the Hebrew language and literature in Andover Theological Seminary in 1883-1902, and was president of its faculty in 1899-1901; in 1902 he became professor of theology and in 1904 professor of the history of religion at Harvard University. His chief critical work dealt with the Hexateuch, and more particularly the Book of Judges (Commentary, 1895; text, translation and notes, 1898; text with critical notes, 1900).

MOORE, HENRY (1831-1895), English painter, the ninth son of William Moore, of York, and brother of Albert Joseph Moore, was born in that city on the 7th of March 1831. His artistic education was chiefly supervised by his father, but he also attended the York School of Design, and worked for a short time in the Royal Academy Schools. He first exhibited at the Academy in 1853, and was a constant contributor to its exhibitions. He was past master of the Putnam Presbyterian Church, Zanesville, Ohio. He was Hitchcock professor of the Hebrew language and literature in Andover Theological Seminary in 1883-1902, and was president of its faculty in 1899-1901; in 1902 he became professor of theology and in 1904 professor of the history of religion at Harvard University. His chief critical work dealt with the Hexateuch, and more particularly the Book of Judges (Commentary, 1895; text, translation and notes, 1898; text with critical notes, 1900).

MOORE, HENRY (1831-1895), English painter, the ninth son of William Moore, of York, and brother of Albert Joseph Moore, was born in that city on the 7th of March 1831. His artistic education was chiefly supervised by his father, but he also attended the York School of Design, and worked for a short time in the Royal Academy Schools. He first exhibited at the Academy in 1853, and was a constant contributor to its exhibitions. He was past master of the Putnam Presbyterian Church, Zanesville, Ohio. He was Hitchcock professor of the Hebrew language and literature in Andover Theological Seminary in 1883-1902, and was president of its faculty in 1899-1901; in 1902 he became professor of theology and in 1904 professor of the history of religion at Harvard University. His chief critical work dealt with the Hexateuch, and more particularly the Book of Judges (Commentary, 1895; text, translation and notes, 1898; text with critical notes, 1900).
of the Royal Society of Painters in Water Colours in 1876, and a full member in 1880; an associate of the Royal Academy in 1885; and an academician in 1893; and at Paris, in 1897, where he exhibited "The Newhaven Packet" and "The Heaviness after Raining," he received a third prize and the medal of the Legion of Honour. He died at Margate on the 22nd of June 1897. His works are marked by admirable appreciation of nature, and by a rare understanding of wave-form and colour, and of the subtleties of atmospheric effect; and as a sea-painter he may fairly be regarded as almost without a rival.

MOORE, JOHN (1729-1802), Scottish physician and writer, was born at Stirling in 1729, the son of a clergyman. After taking his medical degree at Glasgow, he served with the army in Flanders, then proceeded to London to continue his studies, and eventually to Paris, where he was attached to the household of the British ambassador. His novel Zeluc (1789), a close analysis of the motives of a selfish profligate, produced a great impression at the time, and indirectly, through the poetry of Byron, has left an abiding mark on literature. Byron said that he intended Childes Harold to be "a poetical Zeluc," and the most striking features of the portrait were undoubtedly taken from that character. Moore's other works have a less marked individuality, but his sketches of society and manners in France, Germany, Switzerland, Italy and England furnish valuable materials for the social historian. In 1792 he accompanied Lord Lauderdale to Paris, and witnessed some of the principal scenes of the Revolution. His Journal during a Residence in France (1793) is the careful record of an eye-witness, and is frequently referred to by Carlyle. He died in London on the 21st of January 1802, leaving five sons, the eldest of whom was General Sir John Moore. James Moore (1753-1834), who wrote Sir John Moore's Life, was also the author of some important medical works, and Sir Graham Moore (1764-1843), saw much active naval service and became an admiral.

MOORE, SIR JOHN (1761-1809), British general, the son of John Moore, was born at Glasgow on the 13th of November 1761. From his early years he intended to become a soldier, learned the Prussian firing exercise, and was "always operating in the field and showing how Geneva could be taken." By the duke of Hamilton's influence he obtained an ensigncy in the 51st foot (1776), learned his drill at Minorca, and in 1778 was appointed captain-lieutenant in a new regiment raised by Hamilton for service in the American War. Moore remained in America to the peace of 1783, after which the Hamilton regiment was disbanded. In 1784 he was returned by the Hamilton interest as member of parliament for the united boroughs of Lanark, Selkirk, Peebles and Linlithgow. In parliament, though he never spoke, he seems to have taken his duties very seriously, and to have preserved an independent position, in which he won the friendship of Pitt and the respect of Burke, and (more important still) the friendship of the duke of York. In 1787 he became major in the 60th (now King's Royal Rifles), but in the following year he was transferred to his old corps, the 51st. In 1792 Moore sailed with his corps to the Mediterranean. He was too late to assist at Toulon, but was engaged throughout the operations in Corsica, and won particular distinction at the taking of Calvi, where he was wounded. Soon after this he became adjutant-general to Sir Charles Stuart, with whom he formed a close friendship. After the expulsion of the French Moore became very intimate with many of the leading Corsican patriots, which intimacy was so obnoxious to Sir Gilbert Elliot (later Lord Minto) that Moore was eventually ordered to leave the island in forty-eight hours, though Elliot wrote in warm terms of his ability. Pitt and the duke of York thought still more highly of Colonel Moore, who was soon sent out to the West Indies in the local rank of brigadier-general. Here he came under the command of Sir Ralph Abercromby, whose most valued adviser and subordinate Moore soon became. In the Santa Lucia expedition he won further distinction by his conduct at the capture of the Vige and Morne Fortuné, and when Sir Ralph left the island he appointed Moore governor and military commander. In 1798 he accompanied Abercromby to Ireland as a major-general, and during the rebellion was actively engaged in command of a corps in the south, defeating a large force of the Irish, and saving Wexford from destruction after the battle of Vinegar Hill (June 21). His services were in universal estimation. In 1799 he was recommended to the command of a brigade destined for the expedition to Holland. At the action of Egmont-op-Zee, on the 2nd of October 1799, his brigade lost very heavily, and he himself was wounded for the fourth time, on this occasion severely. On his return from Holland he was made colonel of the 52nd regiment, with which he was connected for the rest of his career, and which under his supervision became one of the finest regiments in Europe.

Throughout the Egyptian expedition he commanded the reserve. The 28th and 42nd regiments in this corps gained great distinction at the battle of Alexandria, where Moore himself was again wounded. He returned to duty, however, before the surrender of the French forces to General Hutchinson, and added so much to his reputation by his conduct in this brilliant campaign that after the short peace came to an end he was appointed to command the force assembled at Shorncliffe camp (1803) as a part of the army intended to meet the projected invasion of Napoleon. Here were trained some of the best regiments of the service, amongst others the 43rd, 52nd and 93rd Rifles, the regiments which afterwards formed the famous "Light Division" and won in the Peninsula an unsurpassed reputation, not only for the skillful performance of the duties of light troops, but also for their indomitable tenacity in the line of battle. These corps (now represented in the army by the 1st and 2nd battalions of the Oxfordshire Light Infantry and the Rifle Brigade) bore the impress of Moore's training for thirty years and more, and as early as 1804, on account of the "superior state" of the 52nd, the king granted the officers exceptional promotion (August 29, 1804). The system of light infantry tactics taught at Shorncliffe was not invented by Moore; but he had always advocated the creation of these troops, and he supervised the training which produced such great results. While at Shorncliffe he renewed his intimacy with Pitt, who was then residing at Walmer Castle, and his close friendship with Lady Hester Stanhope led to the erroneous belief that he was betrothed to her. On his return to office Pitt caused Moore to be made a Knight of the Bath, and about the same time he made his promotion to the rank of lieutenant-general. Fox, when he succeeded to office, showed the same appreciation of Moore, and in 1806 sent him to the Mediterranean as second-in-command to his brother, General H. E. Fox. In the various minor expeditions of the time Moore had a share, at first as a subordinate, but soon, when Fox went home on account of ill-health, as commander-in-chief of the British army employed in the Mediterranean. About this time he formed an attachment for Caroline Fox (afterwards the wife of Sir William Napier), to whom, however, he did not offer marriage, fearing to "influence her," by his high position and intimacy with her father, "to an irretrievable error for her own future contentment" (Life of Sir C. Napier, i. 39). In 1808 Moore was ordered to the Baltic, to assist Gustavus IV., king of Sweden, against Russia, France and Denmark. The conduct of the king, who went so far as to place Sir John Moore under arrest when he refused to acquiesce in his plans, ruined any chance of successful co-operation, and the English general returned home, making his escape in disguise. He was at once ordered to proceed with his division to Portugal, where he was to be under the command of Sir Hew Dalrymple and Sir Harry Burrard. To Moore, as a general of European reputation, who had held a chief command, the appointment of two senior officers to be over him appeared as a bitter insult, though his resentment did not divert him from his duty. He met his reward, for when, in the excitement caused by the convention of Cintra, Dalrymple and Burrard were ordered home, Moore was left in command of the largest British army that had been employed since the commencement of the war. Wellesley, who returned home with the other generals, showed his appreciation of Moore, and in an interesting letter (Wellington Despatches, Oct. 8, 1808) expressed his desire to use his own
The skilled and able operations which followed this step will be found outlined in the article PENINSULAR WAR. Moore’s advance paralysed the Emperor’s victorious armies. Napoleon himself turned against the British army, which was soon in grave danger, but Spain was saved. Under these circumstances took place the famous retreat on Corunna. The indiscipline of a large proportion of the troops made it painful and almost disastrous, but the reserve under Edward Paget, in which served Moore’s old Stormercliffie regiments, covered itself with glory in the ceaseless rearguard fighting which marked every step of the retreat. The march ended with the glorious battle of Corunna (Jan. 16, 1809), where, early in the day, Sir John Moore received his death wound. He would not suffer his sword to be unbuckled, though the hilt galled his wound, and so he lay—on the field. His last hours were spent in the knowledge of victory . And his only care was to recommend his friends, and those who had distinguished themselves, to the notice of the government. He died with the name of Lady Hester Stanhope on his lips. By his own wish he was buried, before dawn on the 17th, in the ramparts of Corunna. Marshal Soult designed that a monument should be erected, with an inscription framed by himself, and the Spanish general La Romania afterwards carried out Soult’s wishes. The temporary monument thus erected was made permanent in 1811 by Sir Howard Douglas, acting for the prince regent. The duke of York issued to the army on the 1st of February a noble order in which reference was made to the services of the general, and, above all, to the fact that “the life of Sir John Moore was spent among the troops.” A memorial was erected in St. Paul’s Cathedral by order of parliament early in 1809, and his native city of Glasgow erected in George Square a bronze statue by Frazman. The poem by the Rev. Charles Wolfe, “The Burial of Sir John Moore,” became one of the most popular in the language. The best-known portrait of Sir John Moore is that by Sir Thomas Lawrence, P.R.A.

For a few years there was a largely political, raged over the events of the Corunna campaign, and only at a later period has any examination of Sir John Moore’s merits and services been made in a dispassionate spirit. Mistakes were doubtless made in the retreat, but it is sufficient to accept Napoleon’s view that they were probably inseparable from the difficulties with which Moore was surrounded. His greatest claim to renown is, however, independent of his conduct of armies in the field. He was the finest trainer of men that the British army has ever known. He had the true gift of the great man, judgment of character. While Wellington, whose work would have been vain but for Moore’s achievements, perpetually complained of his officers and formed no school, Moore’s name is associated with the career of all who made their mark. The history of the Light Division is sufficient in itself to indicate the results of Moore’s training on the rank and file. In opposition to the majority, who regarded the lash and the gallow as the source of discipline, he sought always and by every means to develop the moral qualities no less than the physical. Of the senior officers Hope, Graham, Edward Paget, Hill and Crawford all felt and submitted to his ascendancy. The flower of the younger generation, Colborne, Hardinge and the Napiers, even though they gained their laurels under Wellington and in chief command, were ever proud to call themselves “Sir John Moore’s men.”

See, besides the works mentioned in the article PENINSULAR WAR, J. C. Moore, Life of Sir John Moore (1833); Sir J. F. Maurice, Sir John Moore’s Journal (1904); and the Records of the 2nd (Oxfordshire Light Infantry). A shorter memoir will be found in Twelve British Soldiers (London, 1899).
Ashbourne, Derbyshire. Moore had to spend much of his time in London, for the popularity of his songs led to an agreement with his publisher to increase the number of them, which he himself at great expense. The invention of his Irish Melodies dates from 1807, and many of the best were written during the three years of his Irish visit. He had already published separate songs, some of them to music of his own, when William Power suggested to him in 1807 the task of fitting words to a series of Irish airs supplied by Sir John Stevenson. He could not have found a task more exactly suited to his powers, and for a quarter of a century he enjoyed a regular income of £500 a year from Power for writing words to music. The first number of the Irish Melodies appeared in 1808, and contained some of his best and most popular work. The rest appeared between 1808 and 1834. In 1816 Stevenson and Moore published Sacred Songs, followed by a second number in 1824. In 1818 they began to adapt melodies from other nations. The first number of National Airs appeared in 1818, and was followed by others in 1820, 1822, 1826, and 1827. After 1812 he broke ground in a new field—political squib-writings. His first butt was the prince regent, once his friend and patron—but tongues, fatherhood, love for cutlets and curacoa, for aged mistresses and practical jokes, were ridiculed with the lightest of clever hands. His earlier political poems appeared in the Morning Chronicle, but in 1813 he published a thin volume of Interceived Letters: The Two peny Post Bag. Other volumes of squibs, most of which passed through several editions, followed: The World at Westminster (1816), The Fudge Family in Paris (1818), The Journal of a Member of the Pococcurante Society (1820), Fables for the Holy Alliance (1823), Odes on Cash, Corn, Catholics, and other Matters (1828), The Fudge Family in England (1835). The only failure among his satirical writings was Tom Crib's Memorial to Congress (1819) for which he had made an elaborate study of thieves' argot.

In 1814 he contracted with the firm of Longmans to supply a metrical romance on an Eastern subject, which should contain at least as many lines as Scott's Rokeby, the publishers binding themselves to pay 3000 guineas on delivery. He had begun Lalla Rookh two years before. He was a careful and laborious writer, and retired to a cottage in the neighbourhood of Donington Park, where with the help of Lord Moira's library he read himself slowly into familiarity with Eastern scenery and manners. He was already far advanced in his work when Byron in The Giaour and again in The Bride of Abydos largely forestalled him. The depression following on the peace of 1815 deferred the publication of Lalla Rookh until 1817. It was an immediate success. The Eastern local colouring which dazzled Moore's contemporaries has, however, faded, and the interest still existing in the poem is chiefly due to the under-current of Irish patriotism which he cleverly worked into it. Immediately after the completion of Lalla Rookh, Moore removed with his family to Slaperton Cottage, Wiltshire, where he was close to Bowood, Lord Lansdowne's country seat. Moore's plans were interrupted by the embezzlement of some £3000 by the deputy he had left in Bermuda, for whose default he was held liable. He hurried to Bermuda and returned to the Continent. He visited Byron in Italy, and in October 1819 received from him the first part of the Memoirs. The continuation was sent to Moore in Paris the next year, with Byron's suggestion that the reversion of the MS. should be sold. Moore did not remain long in Italy, but made his home in Paris, where he was joined by his wife and children. He was not able to return to England until 1822, when the Bermuda affair was compromised by a payment through Longmans of £1000. Moore had had many offers of help, but preferred to be indebted to his publishers only. During his exile he had written another Oriental poem, The Loves of the Angels (1822), which was hardly less popular than Lalla Rookh. He now became a contributor of satirical verse to The Times, the connexion lasting until 1827. He now wrote his Memoirs of the Life of Sheridan, first contemplated in 1814, which appeared, after some delay, in 1825. The Memoirs of Captain Rock (1824), in which he gives a humorous but convincing account of English misgovernment in Ireland, was the result of a tour with Lord Lansdowne in western Ireland. His prose tale, The Epicurean, appeared in 1827, and the Legendary Ballads in 1830. In 1831 he completed his Life and Death of Lord Edward Fitzgerald, probably his best piece of prose work.

The death of Byron in 1824 raised the question of the publication of his Memoirs. Moore had parted with them in 1821 to John Murray for £2000. After they had come into Murray's possession, Moore began to have doubts about the propriety of publishing them, and an arrangement was therefore made that the £2000 should be regarded as a loan, to be repaid during Byron's lifetime, and that the MS. should be retained as a security. When Byron died the Memoirs were still unredeemed, and the right of publication therefore rested with Murray. Moore now borrowed the money from Longmans and induced Murray to give up his claim. The money was paid, and, after a heated discussion with Byron's executors, the MS. was burnt. It was partly the pressure of the debt thus contracted, and partly the expression of wish of Byron, that induced Moore to undertake for the press the editing of The Letters by Lord John Russell, which contains an immense quantity of biographical material; The Poetical Works of Thomas Moore, Collected by Himself (10 vols., 1840-1842); also Notes from the Letters of Thomas Moore to his Music Publisher. Moore published The English Hymn in 1826; was appointed Editor of the Athenaeum in 1827, and was appointed Surveyor and Recorder of Wiltshire in 1832. He was appointed Post Master-General in 1832, but resigned in 1834. Moore's last years were harried by pecuniary difficulties, and by the weakness and misconduct of his sons, the elder of whom retired from the English army to enter the foreign legion of France. After the death of his last child in 1845, Moore became a total wreck, but he lived until the 25th of February 1852. He left sufficient provision for his wife in the Diary which he kept chiefly on her behalf.

His other works are, A Letter to the Roman Catholics of Dublin (1810); A Melologue upon National Music (1811); an operetta, M. P. or The Blue Stocking (1811); A Set of Glee (1817); The Shammer Flie (1831); Evenings in Greece (1826-1832); Travels of an Irish Gentleman in Search of a Religion; Alciphon, a Poem (1839).

See Memoirs, Journal and Correspondence of Thomas Moore (2 vols., 1832-1834); Life and Letters of Thomas Moore (1847), ed. by his daughter; Life and Correspondence of Thomas Moore (1847), ed. by his daughter; Letters of Thomas Moore, Correspondence with his Family (2 vols., 1847-1848), ed. by his daughter; Sentimental, by Thomas Moore, with suppressed passages from the Memoirs of Lord Byron ... (1878), which includes Moore's contributions to the Edinburgh Review (1814-1834). Among modern collections of Moore's Poetical Works may be mentioned that by Charles Kent (the Centenary ed., 1879), and that by W. M. Rossetti (1880). Memoirs of Moore are prefixed to these editions. There are many contemporary references to him, especially in the journals and letters of Byron. There is an excellent life, by Stephen Gwynn, Moore (1897), which includes much material letter. See also monographs on Moore, by G. Vallat and 1895), an essay on the poet " of Irish opposition and revolt " in Georg Brandes, Main Currents in Nineteenth Century Literature (vol. iv., 1975; Eng. trans., 1905).

MOORHEAD, a city and the county-seat of Clay county, Minnesota, U.S.A., opposite Fargo, North Dakota, on the E. bank of the Red River and about 215 m. N.W. of Minneapolis. Pop. (1890), 2088; (1900), 3730; (1910), 4704; (1910),
MOOR-HEN—MOORS

MOOR-HEN,¹ the name by which a bird, often called waterhen and sometimes gallinule, is most commonly known in England. An earlier name was moat-hen, which was inappropriate in the days when a moat was the ordinary adjunct of most considerable houses in the country. It is the Gallinula chloropus of ornithologists, and of the size of a small bantam-hen, but with the body much compressed (as is usual with members of the family Rallidae, to which it belongs), its plumage above is of a deep olive-brown, so dark as to appear black at a short distance, and beneath iron-grey, relieved by some white stripes on the flanks, with the lower tail-coverts of pure white—these last being very conspicuous as the birds swim. A scarlet frontlet, especially bright in the spring of the year, and a red garter on the tibia render it very showy. Though often frequenting the neighbourhood of man, the moor-hen seems unable to overcome the inherent stealthy habits of the Rallidae, and hastens to hide itself on the least alarm; but under exceptional circumstances it may be induced to feed, yet always suspiciously, with tame ducks and poultry. It appears to take wing with difficulty, and may be often caught by an active dog; but, in retreat, it is capable of sustained flight, its longer excursions being chiefly performed by night, when the peculiar call-note it utters is frequently heard as the bird, itself invisible in the darkness, passes overhead. The nest is a mass of flags, reeds, or other aquatic plants, often arranged with much neatness, almost always near the water's edge, where a clump of rushes is generally chosen; but should a mill-dam, sluice-gate, or boat-house afford a favourable site, advantage will be taken of it, and not unfrequently the bough of a tree at some height from the ground will furnish the place for a cradle. The eggs, from seven to eleven in number, resemble those of the coot but are smaller, lighter, and brighter in colour, with spots or blotches of reddish-brown. The common moor-hen is extensively spread throughout the Old World, being found also at the Cape of Good Hope, in India and in Japan. In America it is represented by a very closely allied form, G. galeata, so called from its rather larger frontal helm, and in Australia by another, G. tenera, which generally wants the white flank-markings. Both closely resemble G. chloropus in general habits, as does also the G. pyrrhrohoa of Madagascar, which has the lower tail-coverts buff instead of white. Celebes and Ambonaya possess a smaller cognate species, G. haematopus, with red legs; tropical Africa has the smallest of all, G. angulata. One of the most remarkable varieties is the G. nessiti of Tristan da Cunha,² which has wholly lost the power of flight.³ Among other forms are represented the Gallinula (Erythra) phoenicurus, and Gallinules cristata of India, as well as the South American species classed in the genus Porphyrio, and the remarkable Australian genus Trionyx—contains three species,⁴ which seem to be more terrestrial than aquatic in their haunts and habits.

Allied to all these is the genus Porphyrio, including the bird so named by classical writers, and perhaps a dozen other species often called sultanas and purple water-hens, for they all have a plumage of deep blue—some becoming violet, green, or black in parts, but preserving the white lower tail-coverts, so generally characteristic of the group; and their beauty is enhanced by their scarlet bill and legs. Two, P. allenii of the Ethiopian region and the South American P. porzana, are of small size.

¹ Not to be confounded with "Moor-cock" or "Moor-fowl," names formerly in general use for the red grous.
³ A somewhat intermediate form seems to be presented by the moor-hen of the island of St Denis, to the north of Madagascar (Proc. Zool. Soc., 1867, p. 1036).

Of the larger species, P. caerules is the "Porphyrio" of the ancients, and inhabits certain localities on both sides of the Mediterranean, while the rest are widely dispersed within the tropics, and even beyond them, as in Australia and New Zealand. This latter country has produced a more exaggerated form, Notornis, which has an interesting and perhaps unique history. First described from a fossil skull by Sir R. Owen, and then thought to be extinct, an example was soon after taken alive.⁵ The skin of which (with that of another procured like the first by Walter Mantell) may be seen in the British Museum. Other fossil remains were from time to time noted by Sir R. Owen;⁶ but it began to be feared that the bird had ceased to exist, until a third example was taken about the year 1879, the skin and most of the bones of which, after undergoing examination in New Zealand by Sir W. Buller and T. J. Parker,⁷ found their way to the museum of Dresden, where A. B. Meyer discovered the recent remains to be specifically distinct from the fossil, and while keeping for the latter the name N. montelli gives the former that of N. hochstetteri. What seems to have been a third species of Notornis formerly inhabited Lord Howe's Island, but is now extinct. Whether the genus Aptornis, of which Owen described the remains from New Zealand, was most nearly allied to Notornis and Porphyrio cannot here be decided. T. J. Parker considers it a "development by degeneration of an ocydromine type." (See Ocydrome.) (A. N.)

MOORS (Lat. Mouri; Gr. Maupol, dark men), the name which, as at present used, is loosely applied to any native of Morocco, but in its stricter sense only to the townsmen of the capital. In this sense it is also used of the Mahommedan townsmen in the other Barbary states. It has been by some connected with the Hebrew and Phoenician mahir, western. Wetzstein derives it from mahir, a corruption of Amāsir with its plurals Imāsir and Maśir, archaic forms of the Berber native name Amasigh, the free. From Mouri, the classic name for the north-western African tribes, the north-western districts of that continent came to be called by the Romans Mauretania. The term "Moors" has no real ethnological value. The tribes known to the Romans by that name were undoubtedly of Berber stock (see BERRERS). They first appear in history at the time of the Jugurthine War (110-106 B.C.), when Mauretania west of the Mulucha was under the government of a king called Bocchus, and appears to have constituted a regular and organized state. It retained its independence till the time of Augustus, who in 25 B.C. bestowed the sovereignty of the previously existing kingdom upon Juba II, king of Numidia, at the same time uniting it with the western portion of Numidia, from the Mulucha to the Ampsaga, which received the name of Mauretania Caesariensis, while the province that had previously constituted the kingdom, or Mauretania proper, came to be known as Mauretania Tingitana or Mauretania (see MAURETANIA). With the rest of North Africa Mauretania was overrun by the Arabs in the 7th century. The subsequent conquest of Spain was effected chiefly by Berber tribes, but the Moslems in the peninsula—known to the Christian nations as Moors—always had a strong strain of Arab blood and in most respects became Arabized. The race was also influenced considerably by intermarriage with the natives of Spain, and when the Moors were finally expelled from that country they had become almost entirely distinct from their Berber kinsfolk, to whom they were known as Andalusiens. While the mountainous parts of Morocco continued to be occupied by pure Berber people, the Shihl or Shilluh, the Andalusian Moors flocked to

⁷ Thus the legs-bones and what appeared to him the sternum were described and figured (Trans. vi. and vii. pp. 17, pl. ii. iv.), and the pelvis and another femur (vii. pp. 368, 374, pl. xi), but the supposed sternum afterwards proved not to be that of Notornis, and Owen (Proc. 1882, p. 689) rectified the error, to which his attention had been drawn, and which he had already suspected (Trans. viii. 120).
⁸ Notwithstanding the evidence, which presented some incongruities, offered by Mr Mackay (Ibis, 1867, p. 144).
the coast towns and the plains of Morocco, occupied largely by Arabs. The name Moor is however still applied to the populations speaking Arabic who inhabit the country extending from Morocco to the Senegal, and to the Niger as far east as Timbuktu, i.e. the western Sahara. In this vast region and in all the towns of Barbary many of the Andalusians settled.

The Moors are ethnically a very hybrid race with more Arab than Berber blood. A common mistake is to regard them as a black race, as indicated by the old English phrase “Black-a-Moor,” i.e. black as a Moor. They are a white race, though often sunburnt and bronzed for generations, and both their children and those who have lived in the cities might pass anywhere as Europeans.

The typical Moors of Morocco are a handsome race, with skin the colour of coffee-and-milk, with black eyes and black silky hair, and the features of Europeans. They wear a full beard, and are characterized by a marked dignity of demeanour. There is a general tendency to obesity, which is much admired by the Moors in their women, young girls being stuffed like chickens, with paste-balls mixed with honey, or with spoonfuls of olive oil and sesame, to give them the necessary corpulence. The Moors are an intellectual people, courteous in manner and not altogether unlettered; but they are cruel, revengeful and dogmatic. Among the pirates who infested the Mediterranean were many who were Moors.

They are fanatical Mahomedans, regarding their places of worship as so sacred that the mere approach of a Jew or a Christian is forbidden. The Moors are temperate in their diet and simple in their dress, though among the richer classes of the towns the women cover themselves with silks, gold and jewels, while the men indulge to excess their love of fine horses and splendid arms. The national fault is gross sensuality. The position of women is little better than that of a pampered slavery. They are uneducated, indolent and vicious. Such education as the children receive is of a superficial kind. Slavery flourishes, and slave auctions, conducted like those of cows and mules, take place on the afternoons of stated days, affording a lounge for the rich Moors, who discuss the “goods” offered and seek for bargains. This public sale of slaves was prohibited in the coast towns, c. 1850, under pressure from European powers, but means are found to evade the prohibition.

Of games the young Moors play a great number; the principal one is a kind of football, more like that of Slam and Burma than that of England; wrestling and fencing are popular, but the chief amusement of the adult Moors is the horsemen (la ab el bard), which consists of a type of military tournament, the horsemen going through lance and musket exercises or charging in review fashion, firing volleys as they gallop. Other recreations much in favour throughout Morocco are music, singing, juggling, snake-charming and acrobatic performances. As professional story-tellers many Moors are remarkable, but the national music is monotonous and not very harmonious.

See Dr Arthur Leared, Morocco and the Moors (1891); Budgett Macekn, The Moorish Epic (1899); and The Moors (1902); Frances Macnab, A Ride in Morocco (1902); and see under Morocco; Mauritania; Berbers, &c.

MOOSE, the North American Indian (Algonquian) name of the North American representative of the European elk (q.v.). The word is said to mean “cropper” or “trimmer,” from the animal’s habit of feeding on the branches of trees.

MOOT, a meeting or assembly, in O. Eng. mót, genót, a word of which “to meet” is a derivative. “Moot” or its alternative form “mote” is the common term for the assemblies of the people of the hundred, burgh, &c., in the history of early English institutions, and especially for the national assembly or council, the Witenagemot. The name survives in “moot hall,” the term still given to town-halls and council buildings in some towns in England, as at Aldeburgh. From its meaning of assembly, the word was applied to a debate or discussion, especially of the discussion of a hypothetical case by law students at the Inns of Court. These moots are still carried on at Gray’s Inn. As an adjective, “moot” means doubtful, undecided.

MOOP, a bunch of cloth, rags or coarse yarn, fastened to a pole and serving as a broom or brush for swabbing up wet floors or other surfaces and for cleaning generally. The word is usually taken to be an adaptation of Lat. mappa, cloth, napkin, cf. “map.” A particular application of the term in provincial English is to an annual hiring or statute-fair, as “mop-fair,” at which domestic and agricultural servants out of places attended, carrying a broom, a mop or other implement indicative of their calling.

MOPLAH (Malayalam mappila), a fanatical Mahomedan sect found in Malabar. The Moplahs, who number upwards of a million, are believed to be descended from Arab immigrants, who landed on the western coast of India in the 3rd century after the Hegira. They are remarkable for the fanaticism displayed in successive attacks upon the Hindus, and they have several times resisted British troops. A regiment of the Indian army was recruited among them, but the experiment proved a failure, and the Mooplah Rifles were disbanded in April 1897.

MOPUS, in Greek legend, the name of two seers. (1) Son of Ampyx (or Ampysus) and the nymph Chloris, a Lapith of Oechalia in Thessaly. He took part in the Calydonian boar hunt and accompanied the Argonauts as their prophet. He died from the bite of a serpent which sprang from the blood of the poisoned horseman. He is represented on the chest of Cyptes as boxing with Admetus. He was afterwards worshipped as a hero and an oracle was consecrated to him. (2) Son of Rhacius (or Apollo) and Manto, daughter of Teiresias. The rival seer Calchas is said to have died of chagrin because the predictions of Mopsus were fulfilled, while his own proved incorrect. Together with another seer, Amphilochus, Mopsus founded Mallus in Cilicia after the return from Troy; and in a quarrel for its possession both lost their lives. According to Pausanias (vi. 3, 2) Mopsus expelled the native inhabitants of Caria, and built the town of Colophon. Mopsus was worshipped as a god by the Cilicians, and had two famous oracles at Colophon and Mallus. His name survives in the town of Mopsuestia (Μοψουστία) and the spring of Mopsucrene. Mopsus appears to be the incarnation of Apollo of Claros.

MOQUEGUA, a maritime province of southern Peru, bounded by the departments of Ancash and Puno, and by the republic of Chile. Area, 5550 sq. m.; pop. (1906 estimate), 35,520. The province extends from the Pacific coast eastward to the Cordillera Occidental, which forms the boundary line with the province of Puno, and the range of Bolivia. Eastern Moquegua is volcanic, and is bounded by the magnificent mountain range and western rim of the Ticacca basin. Among the volcanoes in the province are Tutupacu, the last eruption of which occurred in 1822, Huaynaputina and Hachalayhua, which were in violent eruption in 1866, Coporina, Omate, Ubinas and Candarave—the last three still showing signs of activity. This region is also subject to severe earthquake shocks. On the lower slopes of the Cordillera there are fertile irrigated valleys which produce grapes and olives for commercial purposes, and a considerable variety of fruits, cereals and vegetables for local consumption. The best-known grape-producing districts are Moquegua (capital) and Locumba—the product being converted into wine and brandy for export. The capital is Moquegua (pop. about 5000 in 1906), in the upper valley of the Ilo River, 4500 ft. above sea-level, and 50 m. by rail from the small port of Ilo on the Pacific coast.

Moquegua was formerly one of the three provinces forming a department of the same name. The other two provinces (Tacna and Arequipa) were held for indemnity by Chile after the war of 1879–1883 with the understanding (treaty of Ancon, March 8, 1884) that at the expiration of ten years a plebiscite should be taken in the two provinces to determine whether they should remain with Chile, or return to Peru—the country to which they should be annexed to pay the other 10,000,000 pesos. Chile did not comply with this treaty agreement, and in 1910 still held both provinces.

MORA, JOSÉ (1638–1725), Spanish sculptor, was a pupil of Alonso Cano. He died in Granada in 1725 and was buried in
the Albaicin church. His work can be usefully studied in the eight statues in the Capella del Cardenal in the Cordova Cathedral and in the figures of St Bruno and St Joseph in the Cartuja near Granada.

See B. Haendelke, Studien zur Geschichte der spanischen Plastik (Strassburg, 1900).

**Mora**, or Morra (Ital. delay), a game, universally popular in Italy, in which one player endeavors to guess instantly the number of fingers held up by the other. Ancient Egyptian sculptors represent a game of this kind, and it was played by the Romans, who called it *micare digitis*, or finger-flashing. It is known to the Chinese and to certain tribes of the Pacific Islands. There are several methods of playing mora, but in the one most common in Italy the two players, placed face to face, throw out at the same instant one or more fingers of one hand, each crying out simultaneously a number guessed to be that of his adversary's exposed fingers. A correct guess counts one; if both guess correctly or wrongly there is no score. The game, which is generally five or nine points, is played for stakes, and with extraordinary swiftness.

**Moraceae**, in botany, an order of dicotyledons, belonging to the series Urticiflorae, to which belongs also the nettle family (Urticaceae, q.v.). It contains about 60 genera with about 1000 species, mostly trees or shrubs, widely distributed in the

often yields caoutchouc as in species of *Ficus* (e.g. *F. elastica*), *Ceropis* (q.v.), a tropical American genus with thirty to forty species, and others.

**End of Shoot showing Stipule, s, of India-rubber Plant (Ficus elastica).**

The leaves, which are entire or more or less divided, are stipulate, the stipules being small and lateral as in *Morus* and allied genera or intrapteriolar, each pair uniting to form a cap round the younger leaves, as in *Ficus* and allied genera, and very well shown in *F. elastica*, the common india-rubber plant of greenhouses. The plants are monocious or dioecious, and the small unisexual flowers are borne in cymose inflorescences which are condensed into apparent racemes, spikes or heads. In the fig they coalesce to form a fleshy hollow axis on the inner face of which the flowers are situated, while in *Dorstenia* they form a flat, often lobed, expansion with the flowers sunk on the upper face. The flower resembles

![Fig (Ficus carica), Shoot bearing Leaves and Fruit.](image)

1. Inflorescence cut lengthwise to show the numerous flowers crowded on the inner surface.
2. A female flower, enlarged.
3. Fruit cut lengthwise.

![Mulberry (Morus nigra), Shoot bearing Leaves and Fruit.](image)

1. Cattkin of male flowers.
2. One male flower.

that of Urticaceae; there are generally four free or more or less united perianth leaves, with, in the male flower, a stamen opposite each perianth leaf; the filaments are incurred in the mulberry and allied genera and straight in the fig and its allies. *Artocarpus* has only one stamen. The female flower contains two carpels in the median plane, the posterior one of which is often more or less aborted. Each developed ovary chamber contains a solitary pendulous more or less curved ovule. The fruit is an achene or drupe, often surrounded by the fleshy perianth and still further complicated by the union of fruits of different flowers as in mulberry, the development of a fleshy receptacle as in fig, or as in *Artocarpus* (breadfruit), by the union of fruits, perianth and axis into a solid fleshy mass. The embryo is generally curved and surrounded by a fleshy endosperm.

From the evidence of leaf-fossils it is probable that the genus *Ficus* existed as far north as Greenland in the Cretaceous era and was generally distributed in North America and Europe in the Tertiary period up to miocene times.

**Moradabad**, a city and district of British India, in the Bareilly division of the United Provinces. The city is on the
right bank of the river Ramganga, 655 ft. above sea-level, and has a station on the Oudh & Rohilkhand railway, 868 miles from Calcutta. Pop. (1901), 75,718. It was founded in 1037 by Rustam Khan, who built the fort and the town on either side of the river bank, and the fine Jain temple or great mosque (1631). The town forms a large centre of trade in country produce. It has a special industry in ornamental brassware, sometimes plated with lac, or tin, which is then engraved. Cotton weaving and printing is also carried on.

The District of Moradabad lies east of the Ganges and west of the native state of Rampur. Area, 2,283 sq. m. The town was long known, and it is said that, when the British entered in 1801, the population was over 1,000,000, showing an increase of 1-1% in the decade. Mahomedans are more numerous than in any other district of the province, forming more than one-third of the total. The principal crops are wheat, rice, millet, pulse, sugar-cane and cotton. The main line of the Oudh & Rohilkhand railway traverses the district from south to north, with branches towards Aligarh and Rampur. A third branch from Moradabad city towards Delhi crosses the Ganges at Garhmukhteshwar by a bridge of eleven spans of 200 ft. each.

MORAES, FRANCISCO DE (c. 1500–1572), Portuguese romance writer, was probably born at the close of the 15th century. We know very little of his life, except that he was treasurer of the household to King John III., and he is first found in Paris in the suite of the Portuguese ambassador, D. Francisco de Noronha, who had gone there in 1542. He was a commander of the Order of Christ, and was called O Palmeirim on account of the authorship of his famous romance of chivalry Palmeirim de Inglaterra, in 1572 he was assassinated at Evora. He appears to have written in France (perhaps in Paris) in 1544, dedicating it to the Infanta D. Maria, daughter of King Manoel, but the first extant Portuguese edition only came out in 1567. A Spanish version was published as early as 1548, and on the strength of this many critics have contended that the book was originally written in that language and that Moraes only translated it into Portuguese. Both tradition and a critical examination of the Portuguese and Spanish texts, however, tell overwhelmingly in favour of the first being the original with Moraes as its author. The episode of the four French ladies shows an intimate acquaintance with the court of Francis I., where Moraes spent some years, and one of these ladies named Tors is the only one loved and to whom he addressed some verses entitled "Descula de huns amores." The Palmeirim de Inglaterra belongs to another branch of the same cycle as the Amadis de Gaula; the two romances are the best representatives of their class, and for their merits were spared from the autor da fia, to which they were condemned other romances of chivalry in D. Quixote. It has a well-marked plot, clearly drawn characters, and an admirable style, and has been reckoned a Portuguese classic from the time of its issue.

Bibliography.—The Palmeirim de Inglaterra, by W. E. Purser (Dublin, 1904), contains an exhaustive study of the romance and the controversy concerning its authorship, with a sketch of the plot. The existing Portuguese editions bear the dates 1567, 1592, 1786, and 1852; translations exist in Spanish, Italian and French. An English version from the French by A. Munday was first published in 1809. In 1807 Robert Southey issued in 4 vols. a complete translation from the Portuguese which is really a revision of Munday. In addition Moraes wrote some Dialogues, which were published at Evora in 1624 and are incorporated in the last two editions of Palmeirim de Inglaterra.

(E. Pr.)

MORAINE, a term adopted from the French for the rocky material carried downwards on the outside of a glacier, and deposited at its sides and foot. The position of the moraine with regard to the glacier is indicated by the names applied to it. The lateral moraine is the fringe of rock fragments at the glacier side. The glacier is always slowly moving down the valley. There are always points in the valley where rock falls are more frequent than in other places. The glacier as it moves forward carries this material and carries it onward in a long heaped line distributing it evenly all down the valley sides. When two glacial valleys converge into one valley two lateral moraines unite at the point of junction and form a median moraine in the resultant broader glacier, which now has two lateral moraines and one median. All this material carried by the glacier is deposited where the glacier ends, and forms the terminal moraine, frequently in the form of a crescentic dam across the valley. This material is carried farther downwards by stream action and distributed; otherwise the end of all glacier valleys would be blocked with débris against which the ice would be piled to a great height, and the glacier would finally become stationary. The material pushed forward from the sides of the glacier is called the lateral moraine, and the material thrown up against the part left beneath the ice the terminal moraine, that carried to the edge and dropped the dump moraine, and that carried forward the push moraine. (See GLACIER.)

MORAN, EDWARD (1820–1890), American artist, was born at Bolton, Lancashire, England, on the 19th of August 1820. He emigrated with his family to America at the age of fifteen, and subsequently settled in Philadelphia, where after having followed his father's trade of weaver, he became a pupil of James Hamilton and Paul Weber. In 1862 he became a pupil of the Royal Academy in London; he established a studio in New York in 1872, and for many years after 1877 lived in Paris. He was a painter of marine subjects and examples of his work are in many prominent collections. Among his canvases are thirteen historical paintings, intended to illustrate the marine history of America from the time of Leif Ericson to the return of Admiral Dewey's fleet from the Philippines in 1899. He died in New York City on the 9th of June 1901. His sons (Edward) Percy Moran (b. 1862) and Léon Moran (b. 1864), and his brothers William Moran (b. 1842) and Thomas Moran (q.v.), also became prominent American artists.

MORAN, THOMAS (1837– ), American artist, was born at Bolton, Lancashire, England, on the 12th of January 1837, and emigrated with his parents to America in 1844, the family settling in Philadelphia. After having been apprenticed for some years to a wood-engraver, he studied under his brother Edward and under James Hamilton, in Philadelphia, and later studied in London, Paris and Italy. In 1871 he accompanied Professor F. V. Hayden’s exploring expedition to the Yellowstone, and in 1873 he went down the Colorado with Major J. W. Powell’s famous exploring party; and on these two trips he made sketches for two large pictures, "The Grand Cañon of the Yellow-stone" and "Chasm of the Colorado River," both of which were bought by the United States government and are now in the Capitol at Washington. He became a member of the National Academy of Design in 1884 and of the American Water Color Society. His wife, Mary Nimmo Moran (1842–1900), was born in Strathaven, Scotland, and emigrated to America in 1853; she was also an artist, and was particularly prominent as an etcher.

MORAR, a town of Central India, in the native state of Gwalior, 3 m. E. of Gwalior city. Pop. (1901), 19,179. It was formerly a British military cantonment and residence of a political agent, but in 1886, when the fortress of Gwalior was restored to Sindhia, the troops at Morar were withdrawn to Jhansi, and the extensive barracks were likewise made over to Sindhia. In the Mutiny of 1857 Morar was the scene of one of the most serious uprisings in Central India. It is a centre for local trade, and has an important tanning industry.

MORAT (Ger. Murten), a small town on the east shore of the Lake of Morat, in the Swiss canton of Fribourg, and by rail
MORATALLA, MORATA

14 m. N. of Fribourg or 18½ m. W. of Bern. In 1900 its population was 2265, of whom 1840 were German-speaking and 1960 French-speaking Protestants. It is a most picturesque little town, overlooked by the 13th-century castle and the quaint tower of the Rathaus, while it is still surrounded by its 15th century walls that are studded at intervals with watchtowers. In 1464 it exchanged its position as a free imperial city (enjoyed since 1218) for the rule of the count of Savoy. In 1475 it was taken by the Swiss at the commencement of their war with Charles the Bold, duke of Burgundy, whose ally was the duchess of Savoy. But in 1476 it was besieged by Charles, though it held out till the Swiss army arrived in haste and utterly defeated (22nd June) the Burgundians. An obelisk a little way south-west of the town stands on the site of the bone-house (destroyed by the French in 1798, wherein the remains of many victims had been collected. Morat was ruled in common from 1475 to 1798 by Bern and Fribourg, being finally annexed to Fribourg in 1814. The Lake of Morat has an area of 105 sq. m., and is connected with that of Neuchâtel by way of the Broye canal. On its shores many lake dwellings have been found.

See E. L. Engeler, Der Stadt Murten Chronik (Bern, 1828); G. F. Oechslin, Die Urkunden der Belagerung u. Schlacht von Murten (Freiburg, 1876); H. Wattelet, Die Schlacht bei Murten (Fribourg, 1894).

MORATA, OLYMPIA PULVIA (1526-1555), Italian classical scholar, was born at Ferrara. Her father, who had been tutor to the young princes of the ducal house of Este, was on intimate terms with the most learned men of Italy, and the daughter grew up in an atmosphere of classical learning. At the age of twelve she was able to converse fluently in Greek and Latin. About this time she was summoned to the palace as companion and instructress of the younger but equally gifted Anne, daughter of René, duchess of Ferrara. Olympia's father, having died a convert to Protestantism, she met with a cold reception at the palace, and withdrew to her mother's house. Olympia now embraced the doctrines of Luther and Calvin. About the end of 1550 she married a young student of medicine and philosophy, Andrew Grunthler of Schweinfurt in Bavaria. In 1554 she accompanied Grunthler to his native place, where he had been appointed physician to the garrison of Spanish troops. In 1553 the margrave Albert of Brandenburg on one of his plundering expeditions took possession of Schweinfurt, and was in turn besieged by the Protestants. At length Albert evacuated the place, and Olympia and her husband made their escape. They finally succeeded in reaching Heidelberg (1554), where a medical lecturership had been obtained for Grunthler through the influence of the Erbach family, by whom they had been hospitably entertained during their flight. Here she died on the 25th of October in the following year.

BIBLIOGRAPHY.—The scanty remains of her works—letters, dialogues, Greek verses—were collected and published by Celsio Secundo Curione (1558). Monographs by Caroline Bowles, wife of Robert Southey the poet (1834). J. Bonnet (1850; Eng. trans., Edinburgh, 1854), and R. Turnbull (Boston, 1846); see also Caroline Garey, Daughters of Italy (1866).

MORATALLA, a town of eastern Spain, in the province of Murcia, 40 m. W.N.W. of the city of Murcia. Pop. (1900), 12,680. Moratalla is built on a mountainous peninsula, almost surrounded by the Grande and Benamor rivers, which flow eastward to join the Segura. The town is a labyrinth of narrow, crooked streets, and some of its houses are Moorish in character. Its chief buildings are the modern hospital and theatre, and the 17th-century church. It has manufactures of coarse cloth, spirits and soap. The nearest railway station is Calasparra, 6 m. east, on the Murcia-Albacete railway.

MORATÍN, LEANDRO ANTONIO EULOGIO MELITÓN FERNANDEZ DE (1760-1828), Spanish dramatist and poet, the son of N. F. de Moratín, was born at Madrid on the 10th of March 1760. Though his poetical tastes were early developed, his father apprenticed him to a jeweller. At the age of eighteen Moratín won the second prize of the Academy for a heroic poem on the conquest of Granada, and two years afterwards he attracted more general attention with his Lección poética, a satire upon the popular poets of the day. He was appointed secretary to Cabrera on a special mission to France in 1787. On his return to Spain, Moratín was honored and presented to a sinecure benefice in the diocese of Burgos, and in 1786 his first play, El Viejo y la niña, was produced at the Teatro del Príncipe. Owing to the opposition of the clerical party, it was speedily withdrawn. The prose comedy, El Café o la comedia nueva, given at the same theatre six years afterwards, at once became popular. On the fall of Florida Blanca, Moratín found another patron in Godoy, who provided him with a pension and the means for foreign travel; he accordingly visited England, where he began a prose translation of Hamlet, printed in 1798 but never performed. From England he passed to the Low Countries, Germany, Switzerland and Italy, and on his return to the Peninsula in 1796 was appointed official translator to the foreign office. In 1803 he produced El Borón in its present form; originally written (1791) as a zarzuela, it was shamelessly plagiarized by Andrés de Mendoza, but the recast, a far more brilliant work, still keeps the stage. It was followed in 1804 by La Mogigala, written between 1797 and 1803. This piece was favourably received, and an attempt to suppress it on religious grounds failed. Moratín's crowning triumph in original comedy was El St de las Niñas (1806), which was performed night after night to crowded houses, ran through several Spanish editions in a year, and was soon translated into a number of foreign languages. In 1808 Moratín was involved in the fall of Godoy, but in 1811 accepted the office of royal librarian under Joseph Bonaparte—a false step, which alienated from him all sympathy and compelled him to spend his last years in exile. In 1812 his Escueto de los maridos, a translation of Molière's Ecole des maris, was produced at Madrid, and in 1813 El Médico a Palos (a translation of Le Médicin malgré lui) at Barcelona. From 1814 to 1828 Moratín lived in Italy and France, compiling a work on the early Spanish drama (Orígenes del teatro español). He died at Paris on the 21st of June 1828.

The most convenient edition of his works is that given in vol. ii. of the Biblioteca de autores españoles; this is supplemented by the Obras póstumas (3 vols., Madrid, 1867-1868).

MORATÍN, NICOLÁS FERNANDEZ DE (1737-1780), Spanish poet and dramatist, was born at Madrid in 1737. He was educated at the Jesuit College in Calatayud and afterwards studied law at the university of Valladolid. In 1772 he was called to the bar; four years afterwards he was nominated to the chair of poetry at the imperial college. He died on the 11th of May 1780. A partisan of French methods, Moratín published in 1762 his Desengaño al teatro español, a severe criticism of the national drama, particularly of the auto sacramental; and his protests were partly responsible for the prohibition of autos three years afterwards (June 1765). In 1762 he also published a play entitled La Pelinmetra. Neither the Pelinmetra nor the Lucrecia (1763), an original tragedy still more strictly in accordance with French conventions, was represented on the stage, and two subsequent tragedies, Hormesinda (1770) and Guzmán el Bueno (1777), were played with no great success. In 1764 Moratín published a collection of pieces, chiefly lyrical, under the title of El Poeta, and in 1765 a short didactic poem on the chase (Diana o arte de la caza). His "epic canto" on the destruction of his ships by Cortés (Las Naves de Cortés destruidas) failed to win a prize offered by the Academy in 1777, and was published posthumously (1785). But a better idea of Moratín's talent is afforded by his anecdotical verses and by his Carta histórica sobre el origen y progresos de las fiestas de toros en España.

His works are included in the Biblioteca de autores españoles, vol. ii.

MORATORIUM (from Lat. morari, to delay), a term used to express a legal authorization postponing for a specified time the payment of debts or obligations. The term is also sometimes used to mean the period over which the indulgence or period of grace stretches, the authorization itself being called a moratory law. A moratory law is usually passed in some special period of political or commercial stress; for instance, on several occasions during the Franco-German War the French government passed
moratory laws. Their international validity was discussed at length and upheld in *Rouquet v. Overman*, 1875, L. R. 10 Q. B. 525.

**MORAVIA** (Ger., Mähren; Czech, Morava), a margravate and crownland of Austria, bounded E. by Hungary, S. by Lower Austria, W. by Bohemia and N. by Prussian and Austrian Silesia. Area, 8,833 sq. m. Physically Moravia may be described as a mountainous plateau sloping from south to south, just in the opposite direction of the adjoining Bohemia plateau, which descends from south to north, and bordered on three sides by mountain ranges. On the north are the Sudetes, namely the Altivater Gebirge, with the highest peak the Grosser Schneeberg (4,664 ft.) and the Altivater (4,887 ft.), which sink gradually towards the west, where the valley of the Oder forms a break between the German mountains and the Carpathians. The latter separate Moravia from Hungary. Parallel to the Carpathians are the Margsieber (1315 ft.) and its continuation, the Steinitz Wald (1450 ft.). On the west are the so-called Bohemian-Moravian Mountains, forming the elevated east margin of Bohemia. The principal passes are those at Iglau and Zwiata to Bohemia and the Wlara Pass to Hungary. Almost the whole of Moravia belongs to the basin of the March or Morava, from which it derives its name and which rises within the territory in the Sudetes. It traverses the whole country in a course of 140 m., and enters the Danube near Pressburg. Its principal tributaries are the Thaya, the Hanna, the Iglawa with the Zwiatawa and the Schwarza, &c. The Oder also rises among the mountains in the north-east of Moravia, but soon turns to the north and quits the country. With the exception of a stretch of the March, none of the rivers are navigable. Amongst the mineral springs worth mentioning are the sulphur springs at Ulbersdorf, the saline ones at Luhatschowitz and the alkaline springs at Teplice.

Owing to the configuration of the soil, the climate of Moravia varies more than might be expected in so small an area, so that, while the vine and maize are cultivated successfully in the southern plains, the weather in the mountainous districts is somewhat rigorous. The mean annual temperature at Brünn is 48° F. Of the total area 34.8% is occupied by arable land, 7% by meadows, 5.7% by pasturages, 12% by gardens, 6.5% by vineyards, while 27.4% are forests. The principal products are corn, oats, barley, potatoes, rye, beetroot, hemp, flax, hay and other fodder; forestry is greatly developed; the breed of sheep in the Carpathians is of an improved quality, and the horses bred in the plain of the Hanna are highly esteemed. The mineral wealth of Moravia, consisting chiefly of coal and iron, is very considerable. Coals are extracted at Neudorf, Leitz, Ratishkowitz and Cie; lignite at Rossitz, Oslavan and Mährisch-Ostrau. Iron ore is found at Zpota, Blansko, Adamstal, Wittkowitz, Rossitz and Stefanau. Other minerals found here are graphite, alum, potter's clay and roofing-slate, and, besides, famous silver mines were worked at Iglau during the middle ages. From an industrial point of view Moravia belongs to the foremost provinces of the Austrian Empire. The principal manufactures are woollen, linen, cotton, cast-iron goods, beet-sugar, leather and brandy. The cloth industry was introduced in the 14th century at Iglau, where it soon obtained a great reputation; it developed afterwards at Olmitz, and since the middle of the 18th century it has its principal centre at Brünn. The linen industry is concentrated at Schönberg, Mistek, Wiesenbarg and Heidentisch; while the cotton industry has its principal seat at Sternberg. The chief ironworks are to be found at Wittkowitz, Stefanau, Zpota and Rossitz; while industrial machines are manufactured at Brünn, Blansko and Adamsthal. Large works of earthenware are established at Znaim and Frain.

Moravia had in 1900 a population of 2,433,081 inhabitants, which is equivalent to 284 inhabitants per sq. m. It belongs to the group of old Slavonic states which have preserved their nationality while losing their political independence. Of the total population 71.36% were Slavs, who were scarcely distinguishable from their Bohemian neighbours. The name of Czech, however, is usually reserved for the Bohemians, while the Slavs of Moravia and West Hungary are called Moravians and Slovaks. The Germans form 27.9% of the population, and are found mostly in the towns and in the border districts. Fully 95% of the inhabitants are Roman Catholics, under the ecclesiastical jurisdiction of the archbishop of Olmitz and the bishop of Brünn; 2.7% Protestants and 2% Jews. In educational matters Moravia compares favourably with most of the Austrian provinces. It is well provided with schools of every description, and the number of illiterates is steadily decreasing. The local diet is composed of 100 members, of which the archbishop of Olmitz and the bishop of Brünn are members ex officio. To the Reichsrat at Vienna Moravia sends 36 members. For administrative purposes Moravia is divided into 34 districts and 6 towns, with autonomous municipalities: Brünn (pop., 108,944), the capital, Iglau (24,387), Olmitz (21,933), Znaim (16,261), Kremsier (13,991) and Ungarisch-Bradhadisch (5,137). Other principal towns are Königsfeld (11,022), Göding (10,231), Mährisch-Ostrau (30,125), Witkowitz (19,128), Mährisch-Schönberg (11,636), Wittau (9063), Neutitschein (11,801), Trebatsch (16,738), Prossnitz (24,054), Sternberg (15,105) and Teplitz (10,907).

**History.**—At the earliest period of which we have any record Moravia was inhabited by the Limesi, a people of Thracian extraction. This name has been perpetuated in that of the province in Bohemia. Afterwards it was inhabited by the Germanic Quadi, who accompanied the Vandals in their westward migration; and they were replaced in the 5th century by the Rugii and Heruli. The latter tribes were succeeded about the year 550 A.D. by the Lombards; and these in their turn were soon forced to retire before an overwhelming invasion of Slavs, who on their settlement there took the name of Moravians (German, Mebrannes or Mährer) from the river Morava. These new colonists became the permanent inhabitants of this district, and in spite of the hostility of the Avars on the east founded the kingdom of Great Moravia, which was considerably more extensive than the province now bearing the name. Towards the end of the 8th century they aided Charlemagne in putting an end to the Avar kingdom, and were rewarded by receiving part of it, corresponding to North Hungary, as a fief of the German emperor, whose supremacy they also acknowledged more or less for their other possessions. After the death of Charlemagne the Moravian princes took advantage of the dissensions of the Frankish nobility to establish their independence, and Rastislau (c. 850) even formed an alliance with the Bulgarians and the Byzantine emperor. The chief result of the alliance with the latter was the conversion of the Moravians to Christianity by two Greek monks, Cyril and Methodius, despatched from Constantinople (863). Rastislau finally fell into the hands of Louis the German, who blinded him, and forced him to end his days as a monk; but his successor, Svatopluk (d. 894), was equally vigorous, and extended the kingdom of Great Moravia to the Oder in the west and the Gran on the east. At this period there seemed a strong probability of the junction of the north-western and south-eastern Slavs, and the formation of a great Slavonic power to east of the German empire. This prospect, however, was dissipated by the invasions of the Magyar hordes in the 10th century, the brunt of which was borne by Moravia. The invaders were encouraged by the German monarchs and aided by the dispensations and mismanagement of the successors of Svatopluk, and in a short time completely subdued the eastern part of Great Moravia. The name of Moravia was henceforth confined to the district to which it now applies. For a century the possession of this marchland was disputed by Hungary, Poland and Bohemia, but in 1029 it was finally incorporated with Bohemia, and so became an integral part of the German empire. Towards the close of the 12th century Moravia was raised to the dignity of a margravate, but with the proviso that it should be held as a fief of the crown of Bohemia. It henceforth shared the fortunes of this country, and was usually assigned as an appanage to younger members of the Bohemian royal house. In 1410 Jobst, margrave of Moravia, was made emperor of Germany, but died a few months after his election. In 1526, on the death of Louis II. of Hungary Moravia came with the rest
of that prince's possessions into the hands of the Austrian house. During the Thirty Years' War the depopulation of Moravia was so great that after the peace of Westphalia the states-general published an edict giving every man permission to take two wives, in order to "repeople the country." After the Seven Years' War Moravia was united in one province with the remnant of Silesia, but in 1840 it was made a separate and independent crownland. The most noticeable feature of recent Moravian history has been the active sympathy of its inhabitants with the anti-Teutonic home-rule agitation of the Bohemian Czechs.

See Die Länder Österreich-Ungarns in Wort und Bild, vol. 8 (Vienna, 1881-1889, 15 vols.); Die österreichisch-ungarische Monarchie in Wort und Bild, vol 17 (Vienna, 1886-1902, 24 vols.); B. Bretholz, Geschichte Mährens (Brünn, 1893, &c.).

MORAVIAN BRETHREN, or Moravian Church, a Christian communion founded in the east of Bohemia. For some years after the death of John Huss (1415), the majority of his followers were split into two contending factions: the Hussite Wars began; and the net result of the conflict seemed to be that while the Utraquists, content with the grant of the cup to the laity, were recognized by the pope as the national Church of Bohemia (1433), the Hussites, under the leadership of Jan Zizka, who had fled at the battle of Lipan (1434) and ceased to exist. But with this result some of Huss's followers, who wished to preserve his spiritual teaching, were not content. They laid great stress on purity of morals; and convinced that the Utraquist Church was morally corrupt, they founded a number of independent societies, first at Kremisr and Meseritsch in Moravia, and then at Vilhenow, Diwiwisch and Chelic in Bohemia. At this crisis Peter of Chelic became the leader of the advanced reforming party. In ethics he anticipated much of the teaching of Tolstoy; in doctrine he often appealed to the authority of Wycliffe; and in some of its views it is possible to trace the influence of the Waldenses. He interpreted the Sermon on the Mount literally, denounced war and oaths, opposed the union of Church and State, and declared that the duty of all true Christians was to break away from the national church and return to the simple teaching of Christ and His apostles. His followers were known as the Brethren of Chelic, and wore a distinctive dress. His most noted supporter was John Rockycana, archbishop-elect of Prague. With his help Peter of Chelic recommended his works to his hearers, and finally, when these hearers asked him to lead them, he laid their case before King George Poldelbrad, and obtained permission for them to settle in the deserted village of Kunwald, in the barony of Senftenberg. It was here that the new community was founded (1457 or 1458). At their head was Gregory, the patriarch; a layman, said later to be Rockycana's nephew; in Michael Bradacius, the priest of Senftenberg, they found a spiritual teacher; and fresh recruits came streaming in, not only from the other little societies at Kremisr, Meseritsch, Chelic, Vilhenow and Diwiwisch, but also from the Waldenses, the Adamites, the Utraquist Church at Königgratz, and the university of Prague. They called themselves Jednota Bratrska, i.e. the Church or Communion of Brethren; and this is really the correct translation of their later term, Unitas fratrum. At the Synod of Lhota (1467), they broke away entirely from the papacy, elected ministers of their own, and made Michael Bradacius consecrate a bishop of Stephan, a bishop of the Waldenses. At the synod of Reichenau (1495), they rejected the authority of Peter of Chelic, and accepted the Bible as their only standard of faith and practice. In doctrine they were generally broad and radical. They taught the Apostles' Creed, rejected Purgatory, the worship of saints and the authority of the Catholic Church, practised infant baptism and confirmation, held a view on the sacrament similar to that of Zwingli, and, differing somewhat from Luther in their doctrine of justification by faith, declared that true faith was "to know God, to love Him, to do His commandments, and to submit to His will." With the Brethren, however, the chief stress was laid, not on doctrine, but on conduct. For this purpose they instituted a severe system of discipline, divided their members into three classes—the Perfect, the Proficient, and the Beginners, and appointed for each congregation a body of lay elders. For the same purpose they made great use of the press. In 1501 Bishop Luke of Prague edited the first Protestant hymn-book; in 1502 he issued a catechism, which circulated in Switzerland and Germany and fired the catechetical zeal of Luther; in 1565 John Blahoslaw translated the New Testament into Bohemian; in 1579-1593 the Old Testament was added; and the whole, known as the Kralitz Bible, is used in Bohemia still. The constitution was practically Presbyterian. At the head of the Church was a body of ten elders, elected by the synod; this synod consisted of all the ministers, and acted as the supreme legislative authority; and the bishops ruled in their respective dioceses, and had a share in the general oversight. The growth of the Brethren was rapid. In 1540 they spread into Great Poland; in the latter half of the century they opened many voluntary schools, and were joined by many of the nobility; and the result was that by 1600, when Rudolph II, granted the Letter of Majesty, they were half the Protestants in Bohemia and more than half in Moravia.

At the very height of their power, however, they were almost crushed out of existence. The cause was the outbreak of the Thirty Years' War. At the battle of the White Hill (1620) the Bohemian Protestants were routed; they were driven from their homes; the Polish branch was absorbed in the Reformed Church of Poland; and then many fled, some to England, some to Saxony, and some even to Texas. For a hundred years the Brethren were almost extinct. But their bishop, John Amos Comenius (1592-1672), held them together. With an eye to the future, he published their Ratio disciplinae, collected money for the "Hidden Seed" still worshipping in secret in Moravia, and had his son-in-law, Peter Jablonsky, consecrated a bishop, and Peter passed on the succession to his son Daniel Ernest Jablonsky.

The revival of the Moravian Brethren was German in origin. Of the "Hidden Seed" the greater number were Germans; they were probably descended from a colony of German Waldenses, who had come to Moravia in 1480 and joined the Church of the Brethren; and, therefore, when persecution broke out afresh they naturally fled to the nearest German refuge. With Christian David, a carpenter, at their head, they crossed the border into Silesia (1610). With the support of local noblemen, they were received at Berthelsdorf, and, with his permission, built the town of Herrn- 

hut (1722-1727). But under Zinzendorf the history of the Moravians took an entirely new turn. He was a fervent Lutheran of the Pietist type; he believed in Spener's "ecclesiola" conception; and now he tried to apply the conception to the Moravian refugees. For some years he had a measure of success. Instead of reviving Moravian orders at once, the settlers attended the Berthelsdorf parish church, regarded themselves as Lutherans, agreed to a code of "statutes" drawn up by the count, accepted the Augsburg Confession as their standard of faith, and, joining with some Lutheran settlers in a special Communion service in Berthelsdorf (Aug. 13, 1727), had such a powerful unifying experience that modern Moravians regard that day as the birthday of the renewed Moravian Church. From that period two conflicting ideals were at work among the Moravians. In form the Moravian Church was soon restored. Before long persecution broke out against Herrnhut; the count sent a band of troops to put down the sect, and as these emigrants would not require their own ministers, he had David Nitschmann consecrate a bishop by Jablonsky (1735). In this way the Moravian orders were maintained; the "ecclesiola" became an independent body, and the British parliament recognized the Brethren as "an ancient Protestant Episcopal Church" (1749, 22 Geo. II. cap. 120). And yet, on the other hand, Zinzendorf's conception continued long in force. It hampered the Brethren's progress in Germany, and explains the smallness of their numbers there. Instead of aiming at Church extension, they built settlements on the estates of friendly noblemen, erected Brethren's and Sisters' houses, and cultivated a quiet type of spiritual life. It is true that they evangelized all over Germany; but this part of their work was known as the Diaspora (1 Pet. i. 1); and the idea
underlying this word is that the Brethren minister to the "scattered" in other Churches without drawing them into the Moravian Church. In Germany, therefore, the importance of the Moravians must be measured, not by their numbers, but by their influence upon other Christian bodies. It was from the Moravians that Schleiermacher learnt his religion, and they even made a passing impression on Goethe; but both these men were repelled by their doctrine of the substitutionary sufferings of Christ.

In reply to the very natural question why the Moravians began their work in England, the answer given by history is that John Wesley, on his voyage to Georgia (1733) met some Moravian emigrants; that on his return he met Peter Boehler, who was on his way to North Carolina; that through Boehler's influence both John and Charles Wesley were "converted" (1738). For a few years they took an active share in the Evangelical Revival (1738-1755); but Zinzendorf's "ecclesiola policy prevented their growth, and not till 1835 did the English Moravians resolve to aim at "the extension of the Brethren's Church." In foreign missions the distinctive feature about the Moravians is, not that they were the first to settle in America (1732), but that these were the first Protestants to declare that the leading province of the kingdom of the brethren was the duty of the Church as such. Hitherto it had been a part of colonial policy. It was this that made their missions so influential.

Present Condition.—I. Enterprises: (1) Foreign missions in Labrador, Alaska, Canada, California, West Indies, Nicaragua, Demerara, Surinam, Cape Colony, Kaffraria, German East Africa, North Queensland, and West Himalaya. (2) Leper Home near Jerusalem (1867). (3) Diocesan societies in France, Belgium, Norway, Russia, Poland. (4) Church extension in Germany, Great Britain, North America. (5) Boarding Schools: German province, 14; British, 7; American, 5. (6) Church Revival in Bohemia, 1884; the Moravian Brethren have since 1889, and the second Moravian Church was founded in 1907.

II. Orders and Constitution.—The orders of the ministry are bishops, presbyters, deacons. But the bishops have no dioceses. Their office is a council to ordain, and to act as "intercessors." The supreme legislative board is the General Synod. It consists of delegates elected by each province, certain ex officio members, and representatives from the mission field. At present the Moravian Church is divided into four provinces, German, British, American, and North and American South (North Carolina). In provincial matters each province is independent, holds its own synods, makes its own laws, and elects its own governing board; but the General Synod meets at least once in ten years at Herrnhut, and its regulations are binding in all the provinces. The foreign missions are managed by a mission board, elected by the General Synod. There is also a standing court of appeal, known as the Synod's Council, and consisting of the Mission Board and four provincial boards. The General Synod represents the Church's representatives in the various countries. In Germany the official title of the Church is Evangelische Brüder-Uniitä; in Austria, Evangelische Brüder-Kirche; in England and America, Moravian Church.

III. The Church, etc.—The General Synod (1909) repeated their old fundamental principle that "the Holy Scriptures are our only rule of faith and practice"; but at the same time they declared that their interpretation of Scripture agreed substantially with the Nicene and Chalcedon councils, and Augustana Confessions, and the Thirty-nine Articles. Since 1879 their leading doctrines have been formulated as follows: (1) the total depravity of man; (2) the real Godhead and real humanity of Christ; (3) justification and redemption as a gift of grace to all believers; (4) good works as fruits of the Spirit; (5) fellowship of believers; (6) second coming of Christ; (7) resurrection of the dead to life or judgment.

IV. Ceremonies.—At morning worship the service consists of a litany, scripture lessons, sermon, singing, extempore prayer. At the evening service a litany is rarely used. The Communion is celebrated once a month. Infant Baptism is practised. There is no subscription to membership; in the case of the unbaptized, adult baptism (not a confession of faith and profession of baptism) is required for admission. Members from other Churches are generally admitted by reception.

V. Church Policy.—As is now held by some Moravians that their Church is "a real media between Anglicanism and Dissent." At the last meeting of the Lambeth Conference (1907) some overtures, on certain conditions, were made for (a) joint consecration of bishops, (b) joint ordination of ministers, (c) interchange of pulpits. In response the Moravians, at the General Synod (1909), welcomed the offer, but also declared their wish (a) to preserve their independence as a "Protestant Episcopal Church"; (b) to co-operate freely as heretofore with other Evangelical Churches. On this question negotiations are still in progress.

LITERATURE.—Gindely, Geschichte der Böhmischen-Brüder (1858); Goll, Quellen u. Untersuchungen zur Geschichte, Böhm. Brüder (1883); Müller, Das Bischofamt der Brüder-Kirche (1888); Zinzendorf als Erneuerer der alten Brüder-Kirche (1900); Die deutschen Katechismen d. Böhm.-Brüder (1887); Becker, Zinzendorf und sein Christentum im Verhältnis zur reformierten, lutherischen, und evangelischen Religion (1906); Schulze, Abriß einer Geschichte der Brüder-Mission (1901); Seifert, Church Constitution of the Bohemian and Moravian Brethren (1865); De Schweinitz, History of the Unions Prätum (1885); Wauer, Beginnings of the Brethren's Church in England (1901); Hamilton, History of the Moravian Church in the 18th and 19th Centuries (1906); Hutton, History of the Moravian Church (1909); Moravian Church Book (1902); Moravian Almanac (annual). For other sources see articles "Böhmische-Brüder" and "Zinzendorf" in Hauck's Realencyklopaedie; and for latest results of historical research, Zeitschrift für Brüdergeschichte (half-yearly).

MORAY: THOMAS RANDOLPH, 1ST EARL OF (d. 1332), Scottish warrior and statesman, was the only son of Thomas Randolph of Nithsdale, who had been chamberlain to Scotland, and through his mother Lady Isabel Bruce he was nephew to King Robert the Bruce. Randolph joined Bruce after the murder of the Red Cymyn, and was present at his coronation in 1306. In June of that year he was captured by Aymer de Valence in a fight at Methven, and saved his life by becoming Edward's man. He joined in the hunt forBruce, but in 1308 he was captured by Sir James Douglas and imprisoned. He began by defying his uncle, but presently made his submission, becoming the friendly rival of the exploits of Sir James Douglas and the confidant of Bruce's plans. In 1312 or 1314 the Scottish king made him earl of Moray and lord of Man and Annandale, while the estates held from Edward I. were confiscated. By a brilliant feat of arms he captured and destroyed Edinburgh Castle early in 1314, scaling the rock by a path pointed out by a certain William Francois who had made use of it in a love intrigue. On the eve of Bannockburn Randolph was posted in a wood in charge of the van with orders to prevent the English from throwing cavalry into Stirling. On the approach of the English horse under Sir Robert Clifford, Sir Henry de Beaumanoir, and Sir Thomas Gray, Randolph came out of cover, and his spearmen, drawn up in a square, were vainly attacked on all sides by the English, who were driven to retreat on the appearance of Sir James Douglas with reinforcements; these, however, took no share in the action, the site of which is still known as Randolph's Field. The next day found Randolph in command of the centre of the Scottish battle. He shared in Edward Bruce's expedition to Ireland in 1315, and returned to Scotland in 1317 with Robert Bruce. With Sir James Douglas Randolph was closely allied and the two were associated in a series of brilliant exploits. In 1318 they seized the town of Berwick by escalade; being aided by the treachery of one of the burgesses, Simon of Spalding, and reinforced by Bruce they became masters of the castle some months later. In the next spring they made a raid on the northern English counties, laying waste the country as far as York, where they hoped to seize the English queen. They routed the militia hastily hastened by William de Melton, archbishop of York, in a sight known as the "Chapelfield" massacre of the number of clerics who fell in the battle. Edward II., who was laying siege to Berwick, sought in vain to intercept them on their return journey. Later in the year the two Scottish nobles again raid2d England, and at length Edward II. signed a truce for two years. In 1322 Moray shared in Douglas's exploit at Byland Abbey. In the next year he was one of the Scottish ambassadors charged to conclude a truce with England, and was further sent to Avignon to persuade the pope to acknowledge

1 In general, for "Moray" see Murray, the spelling having been constantly interchangeable. The present early keep the spelling Moray.
Bruce's claims by addressing him as king of Scotland. In the spring of 1326 he was again in France, when he concluded an offensive and defensive alliance between France and Scotland. The death of Bruce in 1329 made Moray regent of Scotland and guardian of the young king David II. In accordance with enactments made by the Scottish parliaments of 1315 and 1318, he died at Musselburgh on the 20th of July 1332, while preparing to resist an invasion by the English barons. Allegations of poisoning are made both by Barbour and Wintoun, but without substantial grounds.

Moray married Isabel, daughter of Sir John Stewart of Bonkyl. His son Thomas, the 2nd earl, was killed at the battle of Dunphins in 1332; his second son John, the 3rd earl, was killed at Neville's Cross in 1346. The earldom then became extinct and the estates passed to their sister Agnes (c. 1312–1359), countess of Dunbar and March, known as "Black Agnes," and celebrated for her gallant defence of Dunbar Castle in 1337 and 1338. (See MARCH, EARLS OF.)

MORBIAN, or Mayurhanj, a native state of India, in the Orissa division of Bengal. Area 4243 sq. m.; pop. (1901), 610,385, showing an increase of 14.7% in the preceding decade; revenue, 654,000. It contains a large proportion of mountainous ground, where wild elephants are numerous, and also some of the richest iron ores in India. The capital is Bairepada (pop. 5613), which is connected by a narrow-gauge line with the Bengal-Nagpur railway.

MORBIHAN, a department of western France on the Atlantic seaboard, formed of part of Lower Brittany, and bounded S.E. by the department of Loire-Inférieure, E. by that of Ille-et-Vilaine, N. by Côtes-du-Nord, and W. by Finistère. Area, 2738 sq. m. Pop. (1906), 573,152. From the Montagnes Noires on the northern frontier the western portion of Morbihan slopes southward towards the Atlantic, being watered by the Blavet, the Blavet with its affluent the Scorf, and the Auray; the eastern portion, on the other hand, dips towards the south-east in the direction of the course of the Oust and its feeders, which fall into the Vilaine. Though the Montagnes Noires contain the highest point (974 ft.) in the department, the most striking orographic feature of Morbihan is the dreary, treeless, streamless tract of moorland and marsh known as the Landes of Launaux, which extends (W. to E.S.E.) WNW. as a width of from 10 to 15 miles for a distance of 31 miles between the valley of the Cliae and that of the Arr (affluents of the Oust). A striking contrast to this district is afforded by the various inlets of the sea, whose shores are clothed with vegetation of exceptional richness, large fig-trees, rose-laurels, and aloes growing as if in Algeria. The coast-line is exceedingly irregular: the mouth of the Vilaine, the peninsula of Ruis, the great gulf of Morbihan (Inner Sea), from which the department takes its name, and the mouth of the Auray, the long Quiberon peninsula attached to the mainland by the narrow isthmus of Fort Penithévere, the deep-branched estuary of Etel, the mouths of the Blavet and the Scorf uniting to form the port of Lorient, and, finally, on the borders of Finistère the mouth of the Laita, follow each other in rapid succession. Off the coast lie the islands of Croix, Belle-Île (q.v.), Hout and Hoedik. Vessels drawing 13 ft. can ascend the Vilaine as far as Redon; the Blavet is canalized throughout its course through the department; and the Oust, as part of the canal from Nantes to Brest, forms a great waterway by Redon, Joscelin, Rohan, and Pontivy. The climate of Morbihan is characterized by great moisture and mildness. Unproductive heath occupies more than a quarter of the department, about a third of which is arable land. Rye, buckwheat and wheat, potatoes and mangels are the chief crops; hemp and flax are also grown. Horned cattle are the chief livestock and bee-keeping is extensively practised. The sea-ware gathered along the coast helps greatly to improve the soil of the region bordering thereon. Outside of Lorient (q.v.), a centre for naval construction, there is little industrial activity in Morbihan. The catching and curing of sardines and the breeding of oysters (Auray, St. Armel, &c.) form the business of many of the inhabitants of the coast, who also fish for anchovies, lobsters, &c., for tinning. The forges of Hennebont are of some importance for the production of sheet-tin.

The department is served by the Orleans railway. It is divided into four arrondissements—Vannes, Lorient, Ploermel and Pontivy—with 37 cantons and 256 communes. The capital Vannes is the seat of a bishopric of the province of Rennes. The department belongs to the region of the Xth army corps and to the académie (educational division) of Rennes, where also is its court of appeal. The principal places are Vannes, Lorient, Ploermel, Pontivy, Auray, Hennebont, Carnac and Locmariaquer, the last two famous for the megalithic monuments in their vicinity. Other places of interest are Erdeven, and Plouharnel, also well known for their megalithic remains; Elven, with two towers of the 15th century, remains of an old stronghold; Josselin, which has the fine château of the Rohan family and a church containing the tomb (15th century) of Olivier de Clisson and his wife; Guern with a chapel of the 15th and 16th centuries and le Faouët with a chapel of the 15th century; Quiberon, which is associated with the disaster of the French éminés in 1795; Sarzeau, near which is the fortress of Suceinio (15th and 16th centuries); Ste Barbe with a chapel, dating from about the end of the 13th century, finely situated, overlooking the Ell; St. Gildas-de-Ruis, with a ruined Romanesque church; the remains of a Benedictine abbey of which Abelard was for a time abbot. The principal pardons (religious festivals) of the department are those of Ste Anne d'Auray and St. Nicolas-des-Eaux.

MORCAR, EARL (fl. 1066), son of Earl Ælfgar, brother of Edwin, earl of the Mercians. They assisted the Northumbrians to expel Tostig, of the house of Godwin, in 1065 and Morcar was chosen earl by the rebels. Harold, Tostig's brother, consented to this extension of the power of the Mercian house. In spite of this concession, and the help which he gave them against Tostig and Harold Hardrada, the two brothers left him to fight alone at Hastings. After trying to secure the crown for their own house, they submitted to William, but lost their earldoms. They attempted to raise the North in 1068, and failed ignominiously. They were pardoned, but Morcar afterwards joined Hereward in the Isle of Ely (1071), while Edwin perished in attempting to raise a Welsh rebellion. Morcar died in prison; at what date is unknown.

See E. A. Freeman, Norman Conquest and William Rufus, vol. i.

MORDECAI BEN HILLEL, a German rabbi, who died as a martyr at Nuremberg in 1298. His great legal (Halachic) work is usually cited as "the Mordecai," and its value consists in its thorough use of the medieval authorities. It acquired wide authority, and was one of the sources of the Code of Joseph Caro. Mordecai was also the author of Responsa.

MORDVINIANS, otherwise called MORDVA, MORDVS, or MORDVINS, a people numbering about one million, belonging to the Ural-Altaic family, who inhabit the middle Volga provinces of Russia and spread in small detached communities to the south and east of these. Their settlement in the basin of the Volga is of high antiquity. One of the two great branches into which they are divided, the Erzya, is perhaps the same as the Aories mentioned by Ptolemy as dwelling between the Baltic Sea and the Ural Mountains. Strabo mentions also the Aorses as inhabitants of the country between the Don, the Caspian Sea and the Caucasus. The Russians made raids on the Mordvins in the 12th century, and after the fall of Kazan rapidly invaded and colonized their country.

The Mordvins are now found in the governments of Simbirsk, Penza, Samara and Nizhni-Novgorod, as well as Saratov and Tambov. But their villages are dispersed among those of the Russians, and they constitute only 10 to 12% of the population in the four first-named governments, and from 5 to 6% in the last two. They are unequally distributed over this area in ethnographical islands, and constitute as much as 23 to 44% of the population of several districts of the governments of Tambov, Simbirsk, Samara and Saratov, and only 2 or 3% in other districts of the same provinces. They are divided into two great...
branches, the Erzya (Erza, or Erza) and the Moksha, differing somewhat in their physical features and language. The southern branch, or the Moksha, have a darker skin and darker eyes and hair than the northern. A third branch, the Karatays, found in Kazan, appears to be mixed with Tatars. The language is a branch of the Western Finnish family, and most nearly allied to the Cheremissian, though presenting many peculiarities (see Finno-Ugrian). The Mordvins have largely abandoned their own language for Russian; but they have maintained a good deal of their old national dress, especially the women, whose profusely embroidered skirts, original hair-dress large ear-rings which sometimes are merely bare-tails, and numerous necklaces covering all the chest and consisting of all possible ornaments, easily distinguish them from Russian women. They have mostly dark hair, but blue eyes, generally small and rather narrow. Their cephalic index is very near to that of the Finns. They are brachycephalous or sub-brachycephalous, and a few are mesaticephalous. They are finely built, rather tall and strong, and broad-chested. Their chief occupation is agriculture; they work harder and (in the basin of the Moksha) are more prosperous than their Russian neighbours. Their capacities as carpenters were well known in Old Russia, and Ivan the Terrible used them to build bridges and clear forests during his advance on Kazan. They now manufacture wooden ware of various sorts. They also make many household articles, and the common wealth of bees is often appears in their poetry and religious beliefs. They have a considerable literature of popular songs and legends, some of them recounting the doings of a king Tushywan who lived in the time of Ivan the Terrible. Nearly all are Christians; they received baptism in the reign of Elizabeth, and the Nonconformists have made many proselytes among them. But they still preserve much of their own mythology, which they have adapted to the Christian religion. According to some authorities, they have preserved also, especially the less Russified Moksha, the practice of kidnapping brides, with the usual battles between the party of the bridegroom and that of the family of the bride. The worship of trees, water (especially of the water-divinity which favours marriage), the sun or Shkay, who is the chief divinity, the moon, the thunder and the frost, and of the home-divinity Kardaserko still exists among them; and a small stone altar or flat stone covering a small pit to receive the blood of slaughtered animals can be found in many houses. Their burial customs seem founded on ancestor-worship. On the fortieth day after the death of a kinsman the dead is not only supposed to return home but a member of his household represents him, and coming from the grave, speaks in his name.

The language is treated of in Ahlquist's Versuch einer Mokchomordwissenschat des Grammatik nebst Texten und Wirter-Verzeichiss (St Peters burg, 1861), and their history, customs and religion by Smirnov (trans. by Boyer). "Les Populations formoises de la Volga (in Publications de l'oeuvres des langues orientales, 4eme, 1898). Much valuable information respecting customs, religion, language and folklore will be found in papers by Paasonen, Helkel, Ahlquist, Mainol and others printed in the Journal de la Société Finno-Ougrienne and the Finnisch-ugrischen Forschungen.

MORE, HANNAH (1745-1833). English religious writer, was born at Stapleton, near Bristol, on the 2nd of February 1745. She may be said to have made three reputations in the course of her life. She was a secretary in the circle of Johnson, Reynolds and Garrick; next, as a writer on moral and religious subjects on the Puritan side; and lastly, as a practical philanthropist. She was the youngest but one of the five daughters of Jacob More, who, though a member of a Presbyterian family in Norfolk, had become a member of the English Church and a strong Tory. He taught a school at Stapleton in Gloucestershire. The elder sisters established a boarding-school at Bristol, and Hannah became one of their pupils when she was twelve years old. Her first literary efforts were pastoral plays, suitable for young ladies to act, the first being written in 1762 under the title of A Search after Happiness (2nd ed. 1773). Metastasio was one of her literary models; on his opera of Attilio regolo she based a drama, The Inflexible Captive, published in 1774. She gave up her share in the school in view of an engagement of marriage she had contracted with Mr Turner. The wedding took place, and, after much reluctance, Hannah More was induced to accept from Mr Turner an annuity which had been settled on her without her knowledge. This set her free for literary pursuits, and in 1772 or 1773 she went to London. Some verses on Garrick's Lear led to an acquaintance with the actor-playwright; Miss More was taken up by Elizabeth Montague; and her unaffected enthusiasm, simplicity, vivacity, and wit won the hearts of the whole Johnson set, the lexicographer himself included, although he is said to have told her that she should "consider what her flattery was worth before she choked him with it." Garrick wrote the prologue and epilogue for her tragedy Percy, which was acted with great success at Covent Garden in December 1777. Another drama, The Fatal Falsehood, produced in 1779 after Garrick's death, was less successful. The Garricks had induced her to live with them; and after Garrick's death she remained with his wife, first at Hampton Court, and then in the Adelphi. In 1781 she made the acquaintance of Horace Walpole, and corresponded with him from that time. At Bristol she discovered a poetess in Mrs Anne Yearsley (1756-1806), a milkwoman, and raised a considerable sum of money for her benefit. "Lactilla," as Mrs Yearsley was called, wished to have a rapid edition of her poems against Miss More, who desired to hold it in trust. The trust was handed over to a Bristol merchant and eventually to the poetess.

Hannah More published Sacred Dramas in 1782, and it rapidly ran through nineteen editions. These and the poems Bas-Bleu and Florio (1786) mark her gradual transition to more serious views of life, which were fully expressed in prose in her Thoughts on the Importance of the Manners of the Great to General Society (1788), and An Estimate of the Religion of the fashionable World (1790). She was intimate with Wilberforce and Zachary Macaulay, with whose evangelical views she was in entire sympathy. She published a poem on Slavery in 1788. In 1785 she bought a house, at Cowslip Green, near Wrington, near Bristol, where she settled down town country life with her sister Martha, and wrote many ethical books and tracts: Strictures on Female Education (1799), Hints towards forming the Character of a Young Princess (1805), Coelebs in Search of a Wife (only nominally a comedy, 1809), Practical Hints (1812) on Christian Morals, Character of St Paul (1815), Moral Sketches (1817). The tone is uniformly animated; the writing fresh and vivacious; her favourite subjects the minor self-indulgences and infirmities. She was a rapid writer, and her work is consequently discursive and formless; but there was an originality and force in her way of putting commonplace sober sense and piety that fully accounts for her extraordinary popularity. The most famous of her books was Coelebs in Search of a Wife, which had an enormous circulation among pious people. Sydney Smith attacked it with violence in the Edinburgh Review for its general priggishness. It is interesting to note that the model Stanley children have been said to be drawn from T. B. Macaulay and his sister. She also wrote many spirited romances and prose tales, the earliest of which was Village Politics (1792), by "Will Chip," to counteract the doctrines of Tom Paine and the influence of the French Revolution. The success of Village Politics induced her to begin the series of Cheap Repository Tracts, which were for three years produced by a subscription paid to her and her sisters at the rate of three a month. Perhaps the most famous of these is The Shepherd of Salisbury Plain, describing a family of phenomenal frugality and contentment. This was translated into several languages. Two million copies of these rapid and telling sketches were circulated in one year, teaching the poor in rhetoric of most ingenuous homeliness to rely upon the virtues of content, sobriety, humility, industry, reverence for the British Constitution, hatred of the French, trust in God and in the kindness of the gentry.

Perhaps the best proof of Hannah More's sterling worth was her indefatigable philanthropic work—her long-continued exertions to improve the condition of the children in the mining districts of the Mendip Hills near her home at Cowslip Green and Barley Wood. The More sisters met with a good deal of
opposition in their good works. The farmers thought that
education, even to the limited extent of learning to read,
would be fatal to agriculture, and the clergy, whose neglet she was
making good, accused her of Methodist tendencies. In her old
age, philanthropists from all parts made pilgrimages to
see the bright and amiable old lady, and she retained all her faculties
till within two years of her death, dying at Clifton, where the last
five years of her life were spent, on the 7th of September 1833.

See The Life of Hannah More, with Notices of Her Sisters (1838), by
is by Sir Leslie Stephen.

MORE, HENRY (1614-1687), English philosopher of the
Cambridge Platonist school, was born at Grantham in 1614.
Both his father and his mother, he tells us, were "earnest
followers of Calvin," but he himself "could never swallow
that hard doctrine." In 1631 he was admitted at Christ's College,
Cambridge, about the time Milton was leaving it. He immersed
himself "over head and ears in the study of philosophy," and
fell into a trance of scepticism, from which he was delivered by
a study of the "Platonic writers." He was fascinated especially
by Neoplatonism, and this fascination never left him.
Theologia germanica also exerted a permanent influence over
him. He took his bachelor's degree in 1635, his master's degree in
1639, and immediately afterwards was chosen fellow of his
college. All other preferment he refused, with one exception.
Fifteen years after the Restoration he accepted a prebend in
Glasgow Cathedral, but only to resign it in favour of his friend
Dr Edward Fowler, afterwards bishop of Gloucester. He would
not accept the mastership of his college, to which, it is understood,
he would have been preferred in 1654, when Cudworth was
appointed. He drew around him many young men of a refined
and thoughtful turn of mind, but among all his pupils the most
interesting was a young lady of noble family. This lady,
probably a sister of Lord Finch, subsequently earl of Nottingham,
a well-known statesman of the Restoration, afterwards became
Lady Conway, and at her country seat at Ragley in Warwick-
shire More continued at intervals to spend a considerable part
of his time. While at Ragley he obtained permission to
amidst the woods of this retreat he composed several of his books.
The spiritual enthusiasm of Lady Conway was a considerable
factor in some of More's speculations, none the less that she at
length joined the Quakers. She became the friend not only of
More and Penn, but of Baron van Helmont and Valentine
Greateakes, mystical theaumaturgists of the 17th century.
Ragley became a centre not only of devotion but of wonder-
working spirituality. 1 From this, his genius suffered, and the
rationality which distinguishes his earlier is much less conspicu-
ous in his later works. He was a voluminous writer both in verse
and in prose, but his works, except the Divine Dialogues (1688),
are now of little interest. This treatise, animated and sometimes
brilliant, is valuable for modern readers in that it condenses his
general view of philosophy and religion.

Henry More represents the mystical and theosophic side of the
Cambridge movement. The Neoplatonic extravagances which
lay hidden in the school from the first, and in its writings to a
head even more exaggerated in his pages. He can never
be praised or criticized. He is, however, save as a spiritual genius and a significant figure in
British philosophy, less robust and in some respects less learned
than Cudworth, but more interesting and fertile in thought, and
more genial in character. From youth to age he describes himself
as gifted with a buoyant temper. His own thoughts were to
him a never-ending source of pleasurable excitement.

This mystical elevation was the chief feature of his character, a certain
radiancy of thought which carried him beyond the common life
without raising him to any artificial height, for his humility and character were not less conspicuous than his piety. The last ten
years of his life were uneventful. He died on the 1st of September
1687, and was buried in the chapel of the college he loved.

Before his death More issued complete editions of his works, his
Opera philosophica in 1675. His Opera omnia was published by
his brother John in 1678. The chief authors for his life are Ward's Life (1710); the prefatory
generalissima prefixed to his Opera omnia (1679); and also a
general account of the manner and scope of his writings in an
alphabetical collection of his Philosophical Poems (1647), in which he "compared his chief speculations and experiences," should also be consulted. An elaborate analysis
of his life and works is given in Tulloch's Rational Theology, vol. ii.
(1852), and there is also a biography of More and vie die Dimension
des Raums (Vienna, 1881). (For his ethical theory, as contained in
the Enchiridion Ethicum, see ETHICS.)

MORE, SIR THOMAS (1478-1555), English lord chancellor,
and author of Utopia, was born in Mill Street in the city
of London, on the 7th of February 1478. He received the rudi-
ments of education at St Anthony's School in Threadneedle
Street, at that time under Nicolas Holt, held to be the best in
the city. He was early placed in the household of Cardinal Morton,
archbishop of Canterbury. Admission to the cardinal's family
was esteemed a high privilege, and was sought as a school of
manners and as an introduction to the world by the sons of the
best families in the kingdom. Young Thomas More obtained
admission through the influence of his father, Sir Thomas, then
a rising barrister and afterwards a justice of the court of king's
bench. The usual procrastination of future distinction is
attributed in the case of More to Cardinal Morton, "who would
often tell the nobles sitting at table with him, where young
More waited on him, whosoever liveth to trie it shall see this
child prove a notable and rare man." At the proper age young
More was sent to Oxford, where he is said vaguely to have
had Cudworth, Grocyn and Linacre for his tutors. 1 All More himself says is that he had Linacre for his master in Greek.
Learning Greek was not the matter of course which it has since become.
Greek was not as yet part of the arts curriculum, and to learn it volun-
tarily was ill looked upon by the authorities. Those who did so
were suspected of an inclination towards novel and dangerous
modes of thinking, then rife on the Continent and slowly finding
their way to England. More's father, who intended his son to
make a career in his own profession, took the alarm; he removed
him from the university without a degree, and entered him at
New Inn to commence at once the study of the law. After com-
pleting a two-years' course in New Inn, an inn of chancery,
More was admitted in February 1496 at Lincoln's Inn, an inn of
court. At that time the Inns of Court and Chancery presented
the discipline of a well-constituted university, and, through
professors under the name of readers and exercises under the
name of mootings, law was systematically taught 2 (CAMPBELL).
In his professional studies More early distinguished himself,
so that he was appointed reader-in-law in Furnival's Inn; but
he would not relinquish the studies which had attracted him in
Oxford. We find him delivering a lecture to audiences of "all
the chief learned of the city of London." A The subject he chose
was a compromise between theology and the humanities, being
St Augustine's De civitatis. In this lecture More sought less to
expound the theology of his author than to set forth the
philosophical and historical contents of the treatise. The
lecture-room was a church, St Lawrence Jewry, placed at his
disposal by Grocyn, the rector.

Somewhere about this period of More's life two things happened
which gave in opposite directions the determining impulse to his
future career. More's was one of those highly susceptible natures
which take more readily and more eagerly than common minds
the impress of that which they encounter on their first contact
with men. Two principal forms of thought and feeling were at
this date in conflict, rather unconscious than declared, on English
soil. Under the denomination of the "old learning," the senti-
ment of the middle ages and the idea of Church authority was

---

1 Life by B. R. 2 Ibid. 3 Roper, Life.
established and in full possession of the religious houses, the universities, and the learned professions. The foe that was advancing in the opposite direction, though without the conscience of a hostile purpose, was the new power of human reason in More's mind. The two are the hostile influences found a congenial home. Each had its turn of supremacy, and in its early years it seemed as if the humanistic influence would gain the final victory. About the age of twenty he was seized with a violent access of devotional rapture. He took a disgust to the world and its occupations, and experienced a longing to give himself over to an ascetic life. He took a lodging near the Charterhouse, and subjected himself to the discipline of a Carthusian monk. He wore a sharp shirt of hair next his skin, scoured himself every Friday and other fasting days, lay upon the bare ground with a log under his head, and allowed himself but four or five hours' sleep. This access of the ascetic malady lasted but a short time, and More recovered to outward appearance his balance of mind. For the moment the balance of his faculties seemed to be restored by a revival of the antagonistic sentiment of humanism which he had imbibed from the Oxford circle of friends, and specially from Erasmus. The dates as regards More's early life are uncertain, and we can only say that it is possible that the acquaintance with Erasmus might have begun during Erasmus's first visit to England in 1499. Tradition has dramatized their first meeting into the story given by Cresacre. Morley against it, and says that each other at the lord mayor's table, that they got into an argument during dinner, and that, in mutual astonishment at each other's wit and readiness, Erasmus exclaimed, "Au tu es Morus, aut nullus," and the other replied, "Au tu es Erasmus, aut diabolus!"

Rejecting this legend, which bears the stamp of fiction upon its face, we have certain evidence of acquaintance between the two men in a letter of Erasmus, with the date "Oxford, 20th October 1499." If we must admit the correctness of the date of Ep. 14 in the collection of Erasmus's Epistolae, we should have to assume that their acquaintance had begun as early as 1497. It rapidly ripened into warm attachment. This contact with the prince of letters revived in More the spirit of the "new learning," and he returned with ardour to the study of Greek, which had been begun at Oxford. The humanistic influence was sufficiently strong to save him from wrecking his life in monkish mortification, and even to keep him for a time on the side of the party of progress. He acquired no inconsiderable facility in the Greek language, from which he made and published some translations. His Latin style, though wanting the imitabile of Erasmus and even the facility against idiom, is yet in copiousness and propriety much above the ordinary Latin of the English scholars of his time.

More's attention to the new studies was always subordinate to his resolution to rise in his profession, in which he was stimulated by his father's example. As early as 1502 he was appointed under-sheriff of the city of London, an office then judicial and of considerable dignity. He first attracted public attention by his conduct in the parliament of 1504, by his daring opposition to the king's demand for money. Henry VII. was entitled, according to feudal laws, to a grant on occasion of his daughter's marriage. But he came to the House of Commons for a much larger sum than he intended to give with his daughter. The members, unwilling as they were to vote the money, were afraid to offend the king, till the silence was broken by More, whose speech is said to have moved the house to reduce the subsidy of three-fifteenths which the Government had demanded to £30,000. One of the chamberlains went and told his master that he had been thwarted by a beardless boy. Henry never forgave the audacity; but, for the moment, the only revenge he could take was upon More's father, whom upon some pretext he threw into the Tower, and he only released him upon payment of a fine of £100. Thomas More even found it advisable to withdraw from public life into obscurity. During this period of retirement the old dilemma recurred. One while he devoted himself to the sciences, "perfecting himself in music, arithmetic, geometry and astronomy, learning the French tongue, and recreating his tired spirits on the viol," or translating epigrams from the Greek anthology; another while resolving to take priest's orders. From dreams of clerical cumbus he was roused by making acquaintance with the family of John Colt of New Hall, in Essex. The "honest and sweet conversation" of the three daughters attracted him, and though his inclination led him to prefer the second he married the eldest, Jane, in 1505, not liking to put the affront upon her of passing her over in favour of her younger sister. The death of the old king in 1509 restored him to the practice of his profession, and to that public career for which his abilities specially fitted him. From this time there was a cause of importance in which he was not engaged. His professional income amounted to £400 a year, equal to £4000 in present money, and, "considering the relative profits of the law and the value of money, probably indicated as high a station as £10,000 at the present day." (Campbell.) It was not long before he attracted the attention of the young king and of Wolsey. The spirit with which he pleaded before the Star Chamber in a case of The Crown v. The Pope recommended him to the royal favour, and marked him out for employment. More obtained in this case judgment against the Crown. Henry, who was present in person at the trial, had the good sense not to resent the defeat, but took the counsel to whose advocacy it was due into his service. In 1514 More was made a judge in the ordinary, knighted, and sworn one of the privy council. He was repeatedly employed on embassies to the Low Countries, and was for a long time stationed at Calais as agent in the shifty negotiations carried on by Wolsey with the court of France. In 1519 he was compelled to resign his post of under-sheriff to the city and his private practice at the bar. In 1521 he was appointed treasurer of the exchequer, and in the parliament of 1523 he was elected Speaker. The choice of this officer rested nominally with the house itself, but in practice was always dictated by the court. Sir Thomas More was pitched upon by the court on this occasion in order that his popularity with the Commons might be employed to carry the money grant for which Wolsey asked. To the great disappointment of the court More remained firm to the popular cause, and it was greatly owing to his influence that its demands were resisted. From this occurrence may be dated the jealousy which the cardinal began to exhibit towards More. Wolsey made an attempt to get him out of the way by sending him as ambassador to Spain. More defended the design by a personal appeal to the king, alleging that the climate would be fatal to his health, and he had little inclination for it. Without already looking round for a more popular successor to Wolsey, more, the graces answer that he would employ More otherwise. In 1525 More was appointed chancellor of the duchy of Lancaster, and no pains were spared to attach him to the court. The king frequently sent for him into his closet, and discoursed with him on astronomy, geometry and points of divinity. This growing favour, by which many men would have been carried away, did not impose upon More. He discouraged the king's advances, showed reluctance to go to the palace, and seemed constrained when there. Then the king began to come himself to More's house at Chelsea, and would dine with him without previous notice. William Roper, husband of More's eldest daughter, mentions one of these visits, when the king after dinner walked in the garden by the space of an hour holding his arm round More's neck. Roper afterwards congratulated his father-in-law on the distinguished honour which had been shown him. "I thank our Lord," was the reply, "I find his grace my very good lord indeed; and I believe he doth as singularly favour me as any subject within this realm. Howbeit, son Roper, I may tell thee I have no cause to be proud thereof; for if my head would win him a castle in France it should not fail to go." As a last resource More tried the expedient of silence, disabling his wit and affecting to be dull. This had the desired effect so far that he was less often sent for. But it did not alter the royal policy, and in 1520, when a successor had to be

1 Life, p. 93.

2 Roper, Life.
found for Wolsey, More was raised to the chancellorship. The selection was justified by More's high reputation, but it was also significant of the modification which the policy of the court was then undergoing. It was a concession to the rising popular party, to which it was supposed that More's politics inclined him. The public favour with which his appointment had been received was justified by his conduct as judge in the court of chancery. Having heard causes in the forenoon between eight and eleven, after dinner he sat again to receive petitions. The manner the supplicant was the more affably he would speak to him and the more speedily he would despatch his case. In this respect he formed a great contrast to his predecessor, whose arrears he soon cleared off. One morning being told by the officer that there was not another cause before the court, he ordered the fact to be entered on record, as it had never happened before. He not only refused all gifts—such as had been usual—himself, but took measures to prevent any of his connexions from interfering with the course of justice. One of his sons-in-law, Heron, having a suit in the chancellor's court, and refusing to agree to any reasonable accommodation, because the judge "was the most affectionate father to his children that ever was in the world," More thereupon made a decree against him.

Unfortunately for Sir Thomas More, a lord chancellor is not only a judge, but has high political functions to perform. In raising More to that eminent position, the king had not merely considered his professional distinction but had counted upon his avowed liberal and reforming tendencies. In the Utopia, which, though written earlier, More had allowed to be printed as late as 1516, he had spoken against the vices of power, and declared for indifferrence of religious creed with a breadth of philosophical view of which there is no other example in any Englishman of that age. At the same time, as he could not be suspected of any sympathy with Lutheran or Wicklifite heretics, he might fairly be regarded as qualified to lead the party which aimed at reform in State and Church within the limits of Catholic orthodoxy. But in the king's mind the public questions of reform were entirely sunk in the personal one of the divorce. The divorce was a point upon which Sir Thomas would not yield. And, as he saw that the marriage with Anne Boleyn was determined upon, he petitioned the king to be allowed to resign the Great Seal, alleging failing health. The royal permission was not refused, and the resignation accepted, on the 10th of May 1532, with many gracious expressions of goodwill on the part of the king. The promise held out of future bounty was never fulfilled, and More left office, as he had entered it, a poor man. His necessitous condition was so notorious that the clergy in convocation voted him a present of £500. This he peremptorily refused, either for himself or for his family, declaring that he had rather see it all cast into the Thames." Yet the whole of his income after resigning office did not exceed £100 a year.

Hitherto he had maintained a large establishment, not on the princely scale of Wolsey, but in the patriarchal fashion of having all his sons-in-law, with their families, under his roof. When he resigned the chancellorship he called his children and grandchildren together to explain his reduced circumstances. "If we wish to live together," said he, "you must be content to be contributors together. But my counsel is that we fall not to the lowest fare first: we will not, therefore, descend to Oxford fare, nor to the fare of New Inn, but we will begin with Lincoln's Inn diet, where many right worshipful men of great account and good years do live full well; which if we find ourselves the first year not able to maintain, then we will in the next year come down to Oxford fare, where many great learned and ancient fathers and doctors are continually conversant, but will our purses stretch not to maintain neither, than may we after, with bag and wallet, go a-begging together, hoping that for pity some good folk will give us their charity."

More was now able, as he writes to Erasmus, to return to the life which had always been his ambition, when, free from business and public affairs, he might give himself up to his favourite studies and to the practices of his devotion. Of the Chelsea interior Erasmus has drawn a charming picture, which may with Holbein's celebrated canvas, "The Household of Sir Thomas More."

"More has built, near London, upon the Thames, a modest yet commodious mansion. There he lives surrounded by his numerous family, including his wife, his son, and his son's wife, his three daughters and their husbands, with eleven grandchildren. There is an abundance of living for to-day, and he has a house full of servants. He loves his old wife as if she were a girl of fifteen. Such is the excellence of his disposition that whatsoever happeneth that could not be helped, he is as cheerful and as well pleased as though the best had been disposed of. He is much fond of children. There he would see that Plato's Academy was revived again, only, whereas in the Academy the discussions turned upon geometry and the power of numbers, the house at Chelsea is a veritable school of Christian religion. In it is none, man or woman, but readeth or studieth the liberal arts, yet their chief care of piety. There is never any idle; the head of the house governs it not by a lofty carriage and of rebukes, but by gentleness and amiable manners. Every member is busy in his place, performing his duty with alacrity; nor is sober mirth wanting."

But More was too conspicuous to be long allowed to enjoy the happiness of a retired life. A special invitation was sent him by the king to attend the coronation of Anne Boleyn, accompanied with a generous offer of occasional presents. More refused to attend, and from that moment was marked out for vengeance. A first attempt made to being him within the meshes of the law only recoiled with shame upon the head of the accusers. They were maladroit enough to attack him on his least vulnerable side, summoning him before the privy council to answer to a charge of receiving bribes in the administration of justice. One Parnell was put forward to complain of a decree pronounced against him in favour of the contending party Vaughan, who he said had presented a gift cup to the chancellor. More stated that he had received a cup as a New Year's gift. Lord Wiltshire, the queen's father, exultingly cried out, "So, did I not tell you, my lords, that you would find this matter true?" "But, my lords," continued More, "having pledged Mrs Vaughan in the wine wherewith my butler had filled the cup, I restored the cup to her." Two other charges of a like nature were refuted as triumphantly. But the very fulness of the accusations must have betrayed to More the bitter determination of his enemies to compass his destruction. For he knew, from his own experience, how, in times of political necessity, to have recourse to that tremendous engine of regal tyranny, the law of treason. A bill was brought into parliament to attain Elizabeth Barton, a nun, who was said to have held treasonable language. Barton turned out afterwards to have been an impostor, but she had duped More, who now lived in a superstitious atmosphere of convents and churches, and he had given his countenance to her supernatural pretensions. His name, with that of Fisher, was accordingly included in the bill as an accomplice. When he came before the council it was at once apparent that the charge of treason could not be sustained, and the efforts of the court agents were directed to draw from More some approbation of the king's marriage. But to this neither cajolery nor threats could move him. The preposterous charge was urged that it was by his advice that the king had committed himself in his book against Luther to an assertion of the pope's authority, whereby the title of "Defender of the Faith" had been gained, but in reality a sword put into the pope's hand to fight against him. More was able to reply that he had warned the king that the very thing might happen, that upon some breach of amity between the crown of England and the pope Henry's too pronounced assertion of the papal authority might be turned against himself, "therefore it were best that place be amended, and his authority more tenderly touched."

"Nay," replied the king, "that it shall not; we are so much bound to the see of Rome that we cannot do too much honour unto it. Whateover impediment be to the contrary, we will set forth that authority to the utmost; for we have received from that see our crown imperial," "which," added More, "till his grace with his own mouth so told me 1 Ep. 426, Appendix."
I never heard before." Anything more defiant and exasperating than this could not well have been said. But it could not be laid hold of, and the charge of treason being too ridiculous to be proceeded with, More's name was struck out of the bill. When his daughter brought him the news, More calmly said, "I' faith, Meg, quod differunt, non auctorit: that which is postponed is not dropt." At another time, having asked his daughter how the court went and how Queen Anne did, he received for answer, "Never better; there is nothing else but dancing and sporting." To this More answered, "Alas, Meg, it pitteth me to remember unto what misery, poor soul, she will shortly come; these dances of hers will prove such dances that she will spurn our heads off like footballs; but it will not be long ere her head will dance the like dance." So the speech runs in the Life by More's great-grandson; but in the only trustworthy record, the life by his son-in-law Roper, More's reply ends with the words, "she will shortly come." In this, as in other instances, the later statement has the appearance of having been an imaginative extension of the earlier.

In 1534 the Act of Supremacy was passed and the oath ordered to be tendered. More was sent for to Lambeth, where he offered to swear to the succession, but steadily refused the oath of supremacy as against his conscience. Thereupon he was given in charge to the abbot of Westminster, and, persisting in his refusal, was four days afterwards committed to the Tower. After a close and even cruel confinement (he was denied the use of pen and ink) of more than a year, he was brought to trial before a special commission and a packed jury. Even so More would have been acquitted, when at the last moment Rich, the solicitor-general, quitted the bar and presented himself as a witness for the Crown. Being sworn, he detailed a confidential conversation he had had with the prisoner in the Tower. He affirmed that, having himself admitted in the course of this conversation "that there were things which no parliament could do—e.g. no parliament could make a law that God should not be God," Sir Thomas had replied, "No more could the parliament make the king supreme head of the Church." By this act of perjury a verdict of "guilty" was procured from the jury. The execution of the sentence followed within the week, on the 7th of July 1535. The head was fixed upon London Bridge. The vengeance of Henry was not satisfied by this judicial murder of his friend and servant; he enforced the confiscation of what small property More had left, expelled Lady More from the house at Chelsea, and even set aside assignments which had been legally executed by More, who foresaw what would happen before the commission of the alleged treason. More's property was settled on Princess Elizabeth, afterwards queen, who kept possession of it till her death.

Sir Thomas More was twice married, but had children only by his first wife, who died about 1511. His only son, John, married an heiress, Ann Cresacre, and was the grandfather of Cresacre More, Sir Thomas More's biographer. His eldest daughter, Margaret (1505-1544), married to William Roper (1496-1578), an official of the court of king's bench and a member of parliament under Henry VIII., Edward VI., and Mary, is one of the foremost women in the annals of the country for her virtues, high intelligence and various accomplishments. She read Latin and Greek, was a proficient in music, and in the sciences so far as they were then accessible. Her devotion to her father is historical; she gave him not only the tender affection of a daughter but the high-minded sympathy of a soul great as his own.

More was not only a lawyer, a wit, a scholar, and a man of wide general reading; he was also a man of cultivated taste, who delighted in music and painting. He was an intimate friend of Holbein, whose first introduction to England was as a visitor to More in his house at Chelsea, where the painter is said to have remained for three years, and where he probably first met Henry VIII. Holbein painted portraits of Sir Thomas and his family. More was beatified by Leo XIII. in 1886.

The Epistle ad Dorpium exhibits More emphatically on the side of the new learning. It contains a vindication of the study of Greek, and of the desirability of printing the text of the Greek Testament—views which at that date required an enlightened understanding to enter into, and which were condemned by the party to which More afterwards attached himself. On the other hand, he can at the most be doubtfully exculpated from the charge of having tortured men and children for heresy. It is admitted by himself that he inflicted punishment for religious opinion. Erasmus only ventures to say in his friend's defence "that while he was chancellor no man was put to death for these pestilent opinions, while so many suffered death in France and the Low Countries." His views and feelings contracted under the combined influences of his professional practice and of public employment. In the Utopia, published in Latin in 1516 (1st English translation, 1551), he not only denounced the ordinary vices of power, but evinced an enlightenment of sentiment which went far beyond the most statesmanlike views of Erasmus, pronouncing not merely for toleration, but rising even to the philosophical conception of the indifference of religious creed. It was to this superiority of view, and not merely to the satire on the administration of Henry VII., that we must ascribe the popularity of the work in the 16th century. For as a romance the Utopia has little interest either of incident or of character. It does not, as has been said, anticipate the economical doctrines of Adam Smith, and much of it is fanciful without being either witty or ingenious. The idea of putting forward political and philosophical principles under the fiction of an ideal state was doubtless taken from Plato's Republic. The Utopia in turn suggested the literary form adopted by Bacon, Hobbes, Filmer, and other later writers; and the name of the book has passed into the language as signifying optimistic but impracticable ideas of reform.

For a bibliography of More's numerous works see the article in the Dict. Nat. Bioq. and the Catalogue of the Alfred Cock collection of portraits and portraits of More, exhibited at the National Portrait Gallery in the summer of 1909. The modern interest in More is illustrated by the reprinting of his 1557 Latin edition of More's Works, but it has been suggested that the Latin original was by Cardinal Morton; as the History of King Richard III., it was edited by J. R. Lumby for the Pitt Press in 1853. The Libellus wereares ... better known as Utopia, was printed at Louvain in 1516, under the superintendence of Erasmus, and appeared in many subsequent editions, many of them of great bibliographical value, the finest being the Basel edition of 1518. It was translated into the chief languages of Europe, and into English by Ralph Robinson as A fruitful and Pleasant Works of the best State of a Pylbique Weale, and of the newe Yle called Utopia (Abraham Nell, 1551); modern editions are by J. Dibdin (2 vols., 1808), Professor Professor Professor in the History of the English Book (1879), by J. Curzon Collins for the Clarendon Press (1904), by R. Steele for the King's Classics (1908), &c. Other translations of Utopia are under the title "A prawne book," "The Soueraynt of the Worlde," "The Colloquies" (William Rastell, 1532) with a "Second Parte" in 1533. The Apologie for Syr Thomas More, written in 1533, is a defence of his own polemical style and of the treatment of heretics by the clergy. A Dialogue of Comfort in Afflictions, printed by Rastell in 1533, was destined primarily for More's family.

More's English works were collected by William Rastell and published as The Worke of Sir Thomas More Knight by Cawood, Ralph Robinson in 1560; the first in English by J. R. Lumby in 1853. The Editiones Lucubrationes were partially collected at Basel 1563 and in 1566 (omnia opera) at Louvain; a fuller edition drawn chiefly from these two appeared at Frankfort and Leipzig in 1689. Modern selections were made by C. M. Robinson (1879), W. F. Walford (1884), by T. E. Bridgham (Wisdom and Will of Blessed Thomas More, London, 1891).
MORÉAS, H. (1826–1898), French painter, was born in Paris on the 6th of April 1826. His father was an architect, who, discerning the lad’s promise, sent him to study under Picot, a second-rate artist but clever teacher. The only influence which really affected Moreau’s development was that of the painter Chassériau (1810–1857), with whom he was intimate when they both lived in the Rue Frochot, and of whom we find reminiscences even in his later works. Moreau’s first picture was a “Pieta” (1852), now in the cathedral at Angoulême. In the Salon of 1853 he exhibited a “Scene from the Song of Songs” (now in the Dijon Museum) and the “Death of Darius” (in the Moreau Gallery, Paris), both conspicuously under the influence of Chassériau. To the Great Exhibition of 1855 he sent the “Athenians with the Minotaur” (“In the Museum at Bourg-en-Bresse”) and “Moses putting off his Sandals within Sight of the Promised Land.” “Oedipus and the Sphinx” began in 1862, and exhibited at the Salon of 1864, marked the beginning of his best period, during which he chose his subjects from history, religion, legend and fancy. In 1865 he exhibited “Medea and Jason” and “The Young Man and Death”; in 1866, the “Head of Orpheus” (“in the Luxembourg Gallery); “Hesiod and the Muse,” a drawing; and “The Peri,” a drawing; “Prometheus” (“in the Moreau Gallery); “Jupiter and Europa,” a “Pietà,” and “The Saint and the Poet,” in 1869. After working in obscurity for seven years, he reappeared at the Salon in 1876 with “Hercules and the Hydra,” “Saint Sebastian,” “Salome Dancing” (“in the Luxembourg by M. Hayem); and in 1878 with “The Sphinx’s Riddle solved,” “Jacob,” and “Moses on the Nile.” Moreau exhibited for the last time at the Salon of 1880, when he contributed “Helen” and “Galatea,” to the Great Exhibition of 1880 he again sent the “Galatea” and “The Young Man and Death.” He took part in the Exposition Universelle of 1889, and was made Knight of the Legion of Honour in 1875 and officer in 1887. He succeeded Delaunay as professor at the École des Beaux Arts, and his teaching was highly popular. When he died, on the 18th of April 1898, he bequeathed to the state his house, containing about 8000 pictures, water-colours, cartoons and drawings, which form the Moreau Gallery, one of the best organized collections in Paris, arranged by M. Rupp, his executor, and, together with Delaunay and Fromentin, one of his closest friends.

See Ayr Renan; Moreau (Paris, 1900); Paul Flat, Le Musée Gustave Moreau (Paris, 1900).

MOREAU, HÉGÉSIPPE (1810–1838), French lyric poet, was born in Paris on the 9th of April 1810. In his early youth his parents, who were poor, migrated to Provins, where the
MOREAU, J. V. M.—MOREAU DE SAINT MÉRY

827

mother went into service and the father took the post of usher in a public school. He went to Paris before 1830, and lived a Bohemian life. He was habitually houseless, and exposed himself to the dangers of a cholera hospital in the great epidemic of 1832 simply to obtain shelter and food. Then he revisited Provins and published a kind of satirical serial called Diogène. Some years of this life entirely ruined his health, and it was only just before his death that he succeeded in getting his collected poems published, selling the copyright for £4 sterling and 80 copies of the book. This volume, Myotis, was received not unfavourably, but the author's death on the 20th of December 1838, in a refuge of the destitute, created an interest in it which was proportionately excessive. Moreau's work has a strong note of imitation, especially in his earlier songs, distinguished from those of his model, Béranger, chiefly by their elegiac note. Some of his poems, such as the elegy La Voulise (1837) and the charming romance La Fermière (1835), have great sweetness and show incontestable poetic power. Moreau wrote some charming prose stories: Le Gui de chèvre, La Souris blanche, &c.;

MOREAU, JEAN VICTOR MARIE (1763-1813), French general, was born at Morlaix in Brittany on the 14th of February 1763. His father was an avocat in good practice, and instead of allowing him to enter the army, as he attempted to do, insisted on his studying law at the university of Rennes. Young Moreau showed no inclination for law, but revelled in the freedom of a student's life. Instead of taking his degree he continued to live with the students as their hero and leader, formed them into a sort of army, which he commanded as their provost, and when 1780 came he commanded the students in the daily affairs which took place at Rennes between the young noblesse and the populace. In 1791 he was elected a lieut.-colonel of the volunteers of Ille-et-Vilaine. With them he served under Dumouriez, and in 1793 the good order of his battalion, and his own martial character and republican principles secured his promotion as general of brigade. Carnot, who had an eye for the true qualities of a general, promoted him to be general of division early in 1794, and gave him command of the right wing of the army under Pichegru, in Flanders. The battle of Tourcoing established his military fame, and in 1795 he was given the command of the Army of the Rhine-and-Moselle, with which he crossed the Rhine and advanced into Germany. He was at first completely successful, won several victories and penetrated to the Isar (see FRENCH REVOLUTIONARY WARS), but at last had to retreat before the archduke Charles. However, the skill he displayed in conducting his retreat—which was greatly enhanced his own reputation, the more so as he managed to bring back with him more than 5000 prisoners. In 1797 he again, after prolonged difficulties caused by want of funds and material, crossed the Rhine, but his operations were checked by the conclusion of the preliminaries of Leoben between Bonaparte and the Austrians. It was at this time he found out the traitorous correspondence between his old comrade and commander Pichegru and the émigré prince de Condé. He had already appeared as Pichegru's defender against imputations of disloyalty, and now he foolishly concealed his discovery, with the result that he has ever since been suspected of at least partial complicity. Too late to clear himself, he sent the correspondence to Paris and issued a proclamation to the army denouncing Pichegru as a traitor. He was dismissed, and it was only when in 1790 the absence of Bonaparte and the victorious advance of Suvârlov made it necessary to have some tried and experienced general in Italy that he was re-employed. He commanded the Army of Italy, with little success, for a short time before being appointed to the Army of the Rhine, and remained with Joubert, his successor in Italy, till Novi had been fought and lost. Joubert fell in the battle, and Moreau then conducted the retreat of the army to Genoa, where he handed over the command to Championnet. When Bonaparte returned from Egypt he found Moreau at Paris, greatly dissatisfied with the Directory both as a general and as a republican, and obtained his assistance in the coup d'état of 18 Brumaire, when Moreau commanded the force which confined two of the directors in the Luxembourg. In reward, the First Consul again gave him command of the Army of the Rhine, with which he forced back the Austrians from the Rhine to the Isar. On his return to Paris he married Mlle Hullot, a Creole of Josephine's circle, an ambitious woman who gained a complete ascendancy over him, and after spending a few glorious weeks with the army in Germany and winning the celebrated victory of Hohenlinden (Dec. 3, 1797) he came down to enjoy the fortune he had acquired during his campaigns. His wife collected around her all who were discontented with the aggrandisement of Napoleon. This "club Moreau" annoyed Napoleon, and encouraged the Royalists, but Moreau, though not unwilling to become a military dictator to restore the republic, would be no party to an intrigue for the restoration of Louis XVIII. All this was well known to Napoleon, who seized the conspirators. Moreau's condemnation was procured only by great pressure being brought to bear by Bonaparte on the judges; and after it was pronounced the First Consul treated him with a pretence of leniency, commuting a sentence of imprisonment to one of banishment. Moreau passed through Spain and embarked for America, where he lived in quiet and obscurity for some years at Morrisville, New Jersey, till news came of the destruction of the grande armée in Russia. Then, probably at the instigation of his wife, he committed the last and least excusable of the series of well-meant political errors that marked his career. Negotiations were set on foot with an old friend in the circle of republican intriguers, Berthier, who, being now crown prince of Sweden and at the head of an army opposite Napoleon, introduced Moreau to the tsar Alexander. In the hope of returning to France to re-establish the régime of popular government, Moreau gave advice to the allied sovereigns as to the conduct of the war, but fortunately for his fame as a patriot he did not live to invade France. He was mortally wounded while talking to the tsar at the battle of Dresden on the 27th of August 1813, and died on the 2nd of September. He was buried at St Petersburg. His wife received a pension from the tsar, and was given the rank of maréchale by Louis XVIII., but his countrymen spoke of his "defection" and compared him to Dumouriez and Pichegru.

Moreau's fame as a general stands very high, though he was far from possessing Napoleon's transcendent gifts. His combinations were skilful and elaborate, and his temper always unruffled when most closely pressed. Moreau was a sincere republican, though his own father was guillotined in the Terror. He was for a long time in mortal health, though he would have been more so had he died in America. He seems by his final words, "Soyez tranquilles, messieurs; c'est mon sort," not to have regretted being removed from his equivocal position as a general in arms against his country.

The literature on Moreau is copious, the best book being C. Jochmus, General Moreau—Abriss einer Geschichte seines Lebens und seiner Feldzüge (Berlin, 1814). A more ordinary work is A. de Besuchamp, Vie politique, militaire, et privée du Général Moreau, avec des notes inédites, etc., published in 1841. The famous account of his death, translated into Russian, was published in 1814, and was translated into English under the title, Some Details Concerning General Moreau and his Last Moments, by Paul Svinin (London, 1814).

MOREAU DE SAINT MÉRY, MÉDÉRIC LOUIS ÉLIE (1750-1819), French politician, was born at Fort de France, in the island of Martinique, on the 28th of January 1750. He came to Paris at the age of nineteen, and became an avocat at the parliament of Paris. He subsequently returned to Martinique to practise law, and in 1780 was appointed member of the colonial council of San Domingo. Returning to Paris in 1784, he received a commission to study the legislation of the French colonies, and published Lois et constitutions des colonies françaises d'Amérique sous le Vent de 1550 à 1785. In 1788 he was president of the assembly of the electors of Paris, played an active part in the early days of the Revolution, and was designated by Martinique deputy to the Constituent Assembly. His moderate ideas were the occasion of his arrest after the 9th of August 1792, but he contrived to escape to the United States, opened
MORECAMBE—MORELL

a bookseller's shop at Philadelphia, and published Description topographique et politique de la partie espagnole et de la partie française de l'Ile de Saint-Domingue (1796-1798). Returning to France in 1799, he became a cartographer to the navy and continued to work on the maritime code. In 1802 he was appointed by the First Consul administrator of the duchies of Parma, Piacenza, and Guastalla, but was dismissed in 1806 for slackness in repressing insubordination. From that date until his death he lived on a pension paid him by the Empress Josephine, who was a kinswoman of his.

See Fournier-Tescay, Discours prononcé aux obsèques de Moreau le 30 Janvier 1819; Silvestre, Notice sur Moreau (Paris, 1819).

MORECAMBE, a municipal borough, water-scarcely and seaport in the Lancaster parliamentary division of Lancashire, England, on Morecambe Bay, 236 m. N.W. by N. from London by the London & North-Western railway; served also by the Midland railway. Pop. (1901), 11,708. A fine promenade extends along the shore; there are a quay and a pier, a winter garden, and all the appointments of a seaside resort. The Midland railway is the harbour authority. The town was incorporated in 1902, and the corporation consists of a mayor, 6 aldermen and 16 councillors. The former alternative name was Poulton-le-Sands. Area, 1,801 acres.

MOREL, the surname of several French classical scholars and printers in the 16th and 17th centuries, known for their editions of classical authors and the Fathers. (1) Guillaume Morel (1503-1564) was born at Tilly-sur-Normandie. After having acted as printer in a Paris firm, he set up for himself, and subsequently succeeded Furne as king's printer in 1555. His most important work was Thessaurus vocum omnium Latinarum, containing a number of quotations from Greek authors, taken from hitherto unpublished MSS. in the Paris library. (2) Frédéric (as he always called himself, not Frédéric Morel, as named the Elder (1525-1583), was born in Champagne. He was of noble family, and was not connected with Guillaume Morel. About 1550 he married the daughter of the famous printer, Michel de Vassosan, in 1557 set up in business in the rue Saint Jean de Beauvais, and in 1571 was appointed printer to the king. His chief publications were the Declarationes of Quintilian and L'Architecture de Philibert Delorme. (3) Frédéric Morel, son of the preceding, named the Younger (1558-1630), was one of the greatest Greek scholars of his time. In addition to the management of his father's business, to which he succeeded, he held the professorship of eloquence at the Collège de France. The number of his translations and commentaries on the Fathers and classical authors (Aristotle, Dión Chrysostom, Strabo) was very large; special mention may be made of his revised edition of Amyot's translation of Plutarch and his Latin translations of some of the dissertations of Maximus of Thèbes, of Lianios, Hierocles and Theon. His commentary on the Psalms is still considered valuable. (4) Claude Morel (1574-1626), brother of the preceding, also published editions of many of the Fathers and other authors, with learned prefaces and notes. (5) Charles Morel (1602-1640) was printer and secretary to the king. He followed the example of the other members of his family, and issued the works of Clement of Alexandria, Gregory of Nazianzus, Cyril, Synesius and Chrysostom, and the Concilia generalia et provincialia of the German theologian Severin Bini. (6) Gilles Morel, brother of the preceding (the dates of his birth and death are unknown), was the last representative of this learned family. The number of his publications was small, but some of them were of great importance, the chief being the Grande bibliothèque des sages, in 17 folio vols. (1643).

See M. Maittaire, Historia typographorum disquisitum partisiam (1717), for all the above; Frédéric Morel the elder is the subject of a monograph by J. Dumoulin (Paris, 1901).

MORELIA (formerly Valladolid), a city of Mexico and capital of the state of Michoacán, 152 m. direct and 234 m. by rail W. by N. of the city of Mexico, near the southern margin of the great Mexican plateau, 6398 ft. above sea-level, in lat. 19° 42' N., long. 100° 54' W. Pop. (1900), 37,728, partly Indians and mestizos. Morelia is served by a branch of the Mexican National railway; its station is outside the city, with which it is connected by a small tramway line. The city is built on a rocky hill rising from the Guayángaro valley, which gives to it a strikingly picturesque appearance. It has the usual rectangular plan, with several pretty squares and straight, clean, well-paved streets. Facing the plaza mayor, now called the Plaza de los Martires because of the execution there of the patriot Matamoros in 1814, is the cathedral, one of the finest specimens of the old Spanish Renaissance church architecture in Mexico.

Among its interior adornments is an onyx font, some fine wood carving in the choir, and the silver doors to the shrines of its chapels. Opposite the cathedral is the government palace, which also contains the public library. The municipal government is housed in an ancient tobacco factory converted to public uses, and a fine old Capuchin convent now serves as a public hospital. The Paseo, or public park, is distinguished for its fine trees and flowers. The Morelianos are noted for their love of music, and musical competitions are held each year, the best band being sent to the city to compete with similar organizations from other states. The public water-supply is brought into the city over a fine old aqueduct (3 m. in length, carried on arches), which was built in 1785 by the bishop of the diocese as a famine relief work. In common with the state of Michoacán, Morelia is a stronghold of clericalism and conservatism. A large number of private schools are maintained throughout the state, with much influence in opposition to the public schools. Notable among these is a large girls' school. Another institution is the college of San Nicolás de Hidalgo, which was founded at Patzcuaro in 1546 by Bishop Quirós and was removed to Valladolid (Morelia) a few years later to be combined with a local college, and was rebuilt in 1882. It is the oldest existing collegiate institution in Mexico; in it Hidalgo once taught and Morelos was a student. The city's manufactures include cotton, woolen and silk textiles, cigars and cigarettes, and dulces, or sweetmeats, Morelia being noted throughout Mexico for the latter, particularly for a variety called Guayabate.

Morelia, first known as Valladolid, was founded in 1541 by Viceroy Mendoza. In 1582 Valladolid replaced Patzcuaro as the capital of Michoacán. It was the birthplace of both Morelos and Iturbide, and was captured by Hidalgo at the beginning of the revolutionary outbreak of 1810-11, and by Iturbide in 1821 when on his march to Mexico City, where he was crowned emperor. Its name was changed to Morelia in 1828, in honour of the revolutionary leader José María Morelos y Pavón, and in 1865 it was made the seat of an archbishop.

MORELL, John Daniel (1856-1891), British educationalist, was born on the 18th of June at Little Baddow, Essex, where his father was minister of the Congregational church (1809-1852). He proceeded to Homerton College in 1833, where he studied theology under Dr Pye Smith. He then entered Glasgow University, where he took his M.A. degree in 1841. Subsequently he studied philosophy and theology under Fichte at Bonn, and returned to England to undertake the pastorate of the Congregational church at Gospot. After three years' work, he decided to give up the ministry in favour of philosophical work. As early as 1846 he made his name by his Historical and Critical View of the Speculative Philosophy of Europe in the Nineteenth Century, which brought him to the notice of Lord Lansdowne, who made him an inspector of schools. From 1848 till 1876 he was active in this capacity. As a result of his experience he published numerous educational works, e.g. The Analysis of Sentences (1852), The Essentials of English Grammar and Analysis (1853), Handbook of Logic (1853), Grammar of the English Language (1857). He also published four lectures on The Philosophical Tendencies of the Age (1848), The Philosophy of Religion (1849), Fichte's Contributions to Moral Philosophy (1860), Philosophical Fragments (1878). An Introduction to Mental Philosophy on the Inductive Method (1884). He died on the 1st of April 1891.
MOREL-LADEUIL—MORELLI

MOREL-LADEUIL, LÉONARD (1820—1888), French goldsmith and sculptor, was born at Clermont-Ferrand. He was apprenticed first to Mord, a manufacturer of bronzes, under whom he became one of the most expert chasers, or ciseleurs, in France, and then to Antoine Vechte, to acquire the art of repoussé (q.v.)—the art in which he was to excel. He studied further under J. J. Feuchère and then attracted the notice of the comte d’Orsay and the duc de Morny, through whose recommendation the French government, desirous of popularizing the idea of the new Imperialism, commissioned him to produce the “Empire Shield.” Napoleon III. notified his warm approval, but the trade, annoyed that a craftsman should obtain commissions direct, resented the innovation and thenceforward boycotted the young artist, whose beautiful and poetic vase, “Dance of the Willis” (the spirits dancing round the vase, above the lake represented on a dish below) none would take. He was encouraged nevertheless by a foreign dealer in Paris, Marchi, who employed him on statuettes, mainly religious in character, until 1859, when Messrs. Eikington, in view of the great exhibition of 1862, engaged him to work in Birmingham for three years in “Night” (reputed to have been made by hot-embossing) and then the “Inventions” vase, which placed him at once at the top of his profession. This was followed by the beautiful plateau called “Dreams,” which was subscribed for (£500) by Birmingham as the town wedding-gift to the prince and princess of Wales. Morel-Ladeuil’s contract was then renewed for five years, but as a matter of fact he remained with the firm for twenty-three years at their London house, the first result being his masterpiece the “Milton Shield: Paradise Lost” (reposed steel and silver), which was the sensation of the Paris Exhibition. It was bought by the English government for £5000, and thousands of copies made by “galvanoplastique” or electrolyte were sold and spread all over the world. Then after “The Months” came another masterpiece, the “Helmet Vase,” in steel, silver, and gold, priced at £6000, which in course of time was presented by the ladies and gentlemen of the royal house to Queen Victoria on her first jubilee. For the Philadelphia Exhibition (1876) Morel-Ladeuil produced “A Pompeian Lady at her Toilet,” following it in 1878 with the “Bunyan Shield,” a companion to the Milton. After putting forth his reliefs “The Merry Wives of Windsor,” “The Merchant of Venice,” and “Much Ado about Nothing,” in view of his failing health he retired to Boulogne, where he died of angina pectoris on the 15th of March 1888, and was buried with much ceremony at Clermont-Ferrand.

His total work, apart from the productions of his youth, numbers 35 pieces, which richly reveal his elegant and refined fancy and grace, his feeling for correct and dainty ornament, and his love of pure art marked by an elevated if rather sentimental taste and a noble style.

MORELLET, ANDRÉ (1727—1819), French economist and miscellaneous writer, was born at Lyons on the 3rd of March 1727. He was one of the last survivors of the philosophes, and in this character he figures in many memoirs, such as Mme de Kémusat’s. He was educated by the Jesuits in his native town, and at the Sorbonne; he then took holy orders, but his designation of abbé was the chief thing clerical about him. He had a ready and biting wit, and Voltaire called him “L’Abbé Mord-Les.” His work was chiefly occasional, and the most notable parts of it were a short pamphlet in answer to Charles Palisot’s scurilous play Les Philosophes (which procured him a short sojourn in the Bastille for an alleged libel on Palisot’s patroness, the princesse de Robec), and a reply to Galiani’s Commerces des blés (1770). Later, he made himself useful in quasi-diplomatic communications with English statesmen, and was pensioned, being, moreover, elected a member of the Academy in 1785. A year before his death in Paris on the 12th of January 1819 he brought out four volumes of Mélanges de littérature et de philosophie du XVIIIe siècle, composed chiefly of selections from his former publications, and after his death appeared his valuable Mémoires sur le XVIIIe siècle et la Révolution (2 vols., 1821).

A bibliography of his numerous works is given in Quérand’s La France littéraire, vol. vi.; see also Sainte-Beuve, Causes des lundis, vol. i.

MORELLI, GIOVANNI (1816—1891), Italian patriot and art critic, was born at Verona on the 10th of February 1816. He was educated first at Bergamo, the home of his mother, who had removed thither on the death of her husband; and then at Aarau in Switzerland. At the age of eighteen he commenced his university career at Munich, being debarred as a Protestant from entering any Italian college, and became the pupil of Ignatius Döllinger, the celebrated professor of anatomy and physiology. Natural philosophy and medicine were the studies to which he specially devoted himself, but he was also keenly interested in all scientific and literary pursuits. At Munich, and later at Erlangen, Berlin and Paris, his brilliant gifts and independence of thought and judgment attracted the attention of the most distinguished men of the day. In Paris he became intimately acquainted with Mme Morel and the influential art critic was not without its effect in determining the direction of his future studies; and, during a summer spent in Switzerland, he formed a friendship with Louis Agassiz, whose teaching made a deep and lasting impression upon him.

On his return to Italy in 1840 he became associated in Florence with that band of patriots who were strenuously labouring for the deliverance of their country from the oppressive Austrian rule. He took an active part in the war of 1848, and was subsequently chosen by the provisional Lombard government to plead the cause of Italian unity before the German parliament at Frankfurt. In 1860, in recognition of the great services rendered to his country by Morelli, Victor Emmanuel named him a citizen of the Sardinian kingdom, and in the following year he was elected deputy for Bergamo to the first free Italian parliament. He was a staunch supporter of Cavour, and, though never a leading politician, exercised a considerable influence over the most prominent statesmen of the Right, who valued his sound judgment, integrity, moderation and foresight. One of his first acts after his election was to draw attention to the urgent need of reform in the administration of matters relating to the fine arts. In consequence of his representations, a commission was appointed with the object of bringing under government control all works of art which could be considered public property. The commission, of which Morelli was named president, began its work in Umbria and the Marches, and he appointed as his secretary G. B. Cavalcaselle, who was then engaged in collecting materials for a work on Italian art. According to one who knew Morelli well, much that Cavalcaselle then learned from his chief was embodied in the well-known History of Painting, which was published in 1864 in conjunction with Sir Joseph Crowe.

The immediate result of Morelli’s first labours in the Marches was the passing of the law, which bears his name, strictly prohibiting the sale of works of art from public and religious institutions. In 1873 he was named a senator of the kingdom of Italy, having voluntarily resigned his seat in the Lower House owing to the increasingly democratic tendencies of the Chamber. In Rome, the seat of the government since 1870, he spent several months of each year; but his settled home was Milan, whither he had removed from Bergamo in 1874. Here he published some of his researches into the history of Italian art. In order to be free to speak his mind unreservedly, he determined to adopt a pseudonym and to write in German. His first contributions, a series of articles on the Borghese Gallery, were published in Lützow’s Zeitschrift für bildende Kunst between the years 1874 and 1886. Posing as an art-loving Russian, who puts forth his opinions with the utmost diffidence, he adopted the pseudonym of Ivan Lermolieff—an anagram of his own name with a Russian termination—and described his essays as Ein kritischer Versuch, translated from the Russian by Johannes Schwarze, this time a Germanized form of Morelli.
The originality of the method recommended by the author for studying art, the general soundness of his critical opinions, and the many new (and apparently correct) attributions suggested for pictures in the Borghese Gallery and elsewhere, attracted the attention of all students of art; but failure attended every attempt to discover the identity of the Russian critic. In 1880 Morelli published a small book under the same pseudonym, entitled, Die Werke italienischer Meister in den Galerien von München, Dresden und Berlin. The appearance of this volume, which was cast in so original a form that it was altogether unlike anything which had preceded it in the realm of art scholarship, created an extraordinary sensation. The daring opinions expressed by the author struck at the roots of all existing art criticism, and were often diametrically opposed to the views of the most renowned art historians of the day. The importance of the work could not be denied, and in spite of determined opposition and searching and bitter attacks, it gained general recognition as a standard work which no serious student of art could ignore. It inaugurated a new and more scientific method of criticism, and marks an epoch in the art study of the 19th century. The book was translated into English in 1883, with Morelli’s own name upon the title-page, and a few years later into Italian. In the decade between 1880 and 1890 he contributed three articles to German periodicals: Perugino oder Raffael, Rafaels Jugendentwicklung, Noch einmal das venezianische Skizzenbuch. Being addressed to critics who had challenged his opinions, they are somewhat polemical in character, but contain a mass of information, more especially about drawings. He also wrote a skit on art connoisseurship in Europe, intending to publish it in English as the reflections of an American on the follies of art critics in the Old World; but he never carried out his intention, though some portion of the MS. was embodied in the first part of his Critical Studies. This volume, the first of a series of three which, under the title of Kunstkritische Studien, was to contain all Morelli’s contributions to art literature, was published in 1890. The first part, cast in dialogue form, contains a detailed exposition of his method. Then follow The Borghese Gallery, a reprint of his former articles with many important additions, and The Doria Gallery, an entirely new contribution. The second volume deals with the galleries of Munich and Dresden, and is a revised edition of the first two parts of the original book of 1880; but here again copious additions rendered it practically a new book. The third volume was to treat of the Berlin Gallery, and was also to contain an exhaustive account of the drawings of Italian masters, but it was destined never to be carried out. Morelli was taken seriously ill towards the middle of February 1891, and was found to be suffering from heart disease and other complications; a fortnight later he died at Milan, on the 28th of February. His collection of drawings by the old masters he bequeathed to his pupil, Dr Frizzi, and his pictures, over 100 in number, to the city of Bergamo, where they are now exhibited as the Galleria Morelli in two rooms of the Accademia Carrara. A striking half-length portrait by Lenbach, who presented it to Morelli and friended in 1886, forms part of the collection. In the library of Morelli a bronze bust of him by a Milanese artist has been placed in the Brera; but his features are more worthily presented in a second portrait by Lenbach and in a life-like pastel sketch executed by the Empress Frederick in 1884, when he was her guest at Baveno. After the death of Morelli the first two volumes of his Critical Studies were published in English, Sir Henry Layard, one of his most intimate friends, contributing to the first a biographical sketch of the author; and the fragmentary MS. of the third volume was published in German by Dr Frizzi, under whose editorship an Italian translation of the first volume has also been issued.

Morelli found art criticism uninspired, unscientific and practically worthless. To be of any real value he held that historical, documentary and traditional knowledge respecting works of art was only of secondary importance as compared with the evidence to be derived from the study of the pictures themselves. He contended that art criticism must be conducted on scientific principles and follow a strict course of inductive reasoning. A painting should be subjected to a critical analysis, and its component parts and minutest details submitted to methodical and exact investigation.

The study of the individual parts and forms was, in his estimation, of the highest importance, for they were not mere incidents, but the outward and visible seal of an artist’s character stamped upon his work, and obvious to all who had eyes to see. By diligent observation of the forms the rudiments of the language of art might be mastered, and the first step taken towards initiating a methodized system of study. The education of a critic consists chiefly in learning to compare, and Morelli soon recognized the value of systematic comparison in the study of art. By the combined methods of critical analysis and comparative observation he found the clue he had so long been seeking. Studying one day in the Uffizi, it suddenly struck him that in a picture by Botticelli containing several figures the drawing of the hands was remarkably similar in all; that the same characteristic but plebeian type, with bony fingers, broad square nails, and dark outlines, was repeated in every figure. Turning to the ears, he observed that these were drawn in an individual manner, and that in the numerous figures in which the ear was visible the same typical form occurred. Having noted these fundamental forms, he proceeded to an examination of other works by this painter, and found that the same forms were exactly repeated, together with other individual traits which seemed distinctive of the master: the characteristic type of head and expression, the drawing of the nostrils, the vitality of movement, the disposition of drapery, harmony of colour (where it had not been tampered with by the restorer), and quality of landscape. In all Botticelli’s true works the presence of these and other characteristics proclaimed their genuineness. In paintings where the forms and types were those of the painter, but where vitality, movement, and all deeper qualities were absent, Morelli recognized works executed from the master’s cartoons; while in pictures where neither types nor forms responded to the test, and where only a general family likeness corresponded with them, he discerned the productions of pupils and imitators. After applying his method to the works of Botticelli, he proceeded to examine those of other Florentine masters, and afterwards of painters of other Italian schools, everywhere meeting with results to him not less convincing.

If the drawing of the hand and ear were not always conspicuous, there were other peculiarities of this language of form to aid in the identification of a master: the treatment of the hair, as in Piero dei Franceschi; the indication of the sinews, as in Foppa; the drawing of the eye, as in Liberale da Verona; the modelling of the eyelid and upper lip, as in Ambrogio de Predis; the form of the feet, as in Luini. In short, all apparently insignificant details were of importance in his plan of study, for to him they were like the signature of the master. (C. F. *)

MORELOS, an inland state of Mexico on the southern slope of the great Mexican plateau, lying S. of the Federal District, with the states of Puebla on the E. and S.E., Guerrero on the S., and Mexico on the W., N. and N.E. Pop. (1900), 161,657, including a large percentage of Indians and mixed races. Area, 2,773 sq. m. Its surface is roughly broken by mountain ranges extending southward from the Sierra de Ajuco, forming numerous valleys opening southward. It is drained by the Amacuzac river, a northern tributary of the Mescalas, or Baissas. There is a wide variation of climate for so small a territory, the higher elevations of the Sierra de Ajuco being cold and humid (the Mexican Central crosses the range at an elevation of 9974 ft.); the lower spurs mild, temperate and healthy, the lower valleys subtropical, hot and unhealthy. The rainfall is light in the lower regions and irrigation is generally employed. Notwithstanding its mountainous character, Morelos is one of the most flourishing agricultural states of Mexico, producing sugar, rice, Indian corn, coffee, wheat, fruit and vegetables. Although the state is supposed to have several of the minerals found in this part of Mexico (silver, cinnabar, iron, lead, gold, petroleum and coal), its mining industries continue undeveloped.
and neglected. San Antonio, a suburb of Cuernavaca, is noted for its pottery, which is highly attractive in form and colour, and finds a ready market among the visitors to that city. Morelos is traversed by two railway lines—the Interoceánico from N.E. to S.W., and the Mexican Central almost N. and S., the latter affording direct communication between the national and state capitals.

The capital, Cuernavaca (pop. 9,584 in 1900), 47 m. S. of the city of Mexico on the Mexican Central railway, is one of the most picturesque towns in Mexico. It dates from the time of Cortés, who built for himself a residence there, and had the town included in the royal grant to himself in 1539. Maximilian had a villa there, and many of the public men of Mexico, natives of the lowlands, have made their homes there rather than in the national capital. The palace of Cortés is now occupied by the state legislature and by various public offices, and Maximilian's villa by a school.

After the capital the largest city in the state is Cuautla Morelos, or Ciudad Morelos (pop. 6,269 in 1900), 27 m. east by south of Cuernavaca, on the Interoceánico railway, and in a rich sugar-producing district. Some of the largest and most modern sugar-mills of Mexico are in the Cuautla district. There are hot sulphur springs here. The town is celebrated in Mexican history for its defense in 1813, of the citizens of Cuautla by José María Morelos (1765–1815), the patriot leader, against a greatly superior royalist force, from the 19th of February to the 2nd of May 1812, when he cut his way through the attacking army and escaped. Other important towns are Yautpec (6,319 in 1900), 16 m. east of Cuernavaca, on the Interoceánico line; Tetecala, 13 m. south-west of the capital, a characteristic Indian town near the pyramid of Xochicalco, and Jojutla, 21 m. south of the capital, on the Interoceánico railway near the southern boundary of the state. An interesting local phenomenon is that of lake Tequesquitan, which was formed by the subsidence of a large area of ground about the middle of the 19th century, carrying with it an old town of the same name. The hollow filled with water, and the spire of the old church is still to be seen in the middle of the lake.

**Moresnet**. A small neutral state lying on the borders of Prussia and Belgium, 4 m. S.W. of Aix-la-Chapelle, and embracing an area of nearly 1,400 acres. Its only village is that of Neutral Moresnet, also called Kelmis or Kalmis, with 2,800 inhabitants. Just over the Prussian frontier is Prussian Moresnet, with 4,539 inhabitants, and in Belgium, Belgian Moresnet, with about 1,200. Moresnet is botanically the best of the three districts. It is botanically beautiful, such as the villa Marti- nengo at Novarino, near Brescia. Among his celebrated works in the city are—the church of S. Clemente, the “Five Virgin Martyrs,” and the “Assumption of the Madonna” (this latter may count as his masterpiece); in S. Nazaro e Celso, the “Coronation of the Madonna” (in S. Maria della Grazie, “St Joseph”; in S. Maria de’ Miracoli, “St Nicholas of Bari.” In the Vienna Gallery is a “St Justina” (once ascribed to Pordenone); in the Städel Institute, Frankfurt, the “Madonna enthroned between Sts Anthony and Sebastian”; in the Berlin Museum, a colossal “Adoration of the Shepherds,” and a large votive picture (one of the master’s best) of the “Madonna and Child,” with infant angels and other figures above the clouds, and below, amid a rich landscape, two priests; in the National Gallery, London, S. Bernardin and other saints and two impressive portraits. If Moretto is stated to have been a man of child-like personal piety, preparing himself by prayer and fasting for any great act of sacred art, such as the painting of the Virgin-mother. His dated works extend from 1524 to 1554, and he was the master of the pre-eminent portrait-painter Moroni. He died on the 22nd of December, 1554.

**Morgagni, Giovanni Battista** (1682–1771), Italian anatomist, was born on the 25th of February 1682 at Forlì.1 His parents were in comfortable circumstances, but not of the nobility; it appears from his letters to G. M. Lancisi that Morgagni was ambitious of gaining admission into that rank, and it may

1 His statue was erected at Forlì in 1875, and the town library preserves fourteen manuscript volumes of his writings.
Morgagni was a man of great erudition in the fields of anatomy, physiology, and medicine, and his work significantly contributed to the advancement of these sciences. His name is synonymous with the term "pathology," which he is credited with coining. Morgagni was born on April 23, 1682, in Bologna, Italy, and died on January 1, 1771, in Padua, Italy. His international reputation is based on his work "De Sedibus et Causis Morborum," which was first published in 1761. This work is often cited as the foundation of modern pathology.

Morgagni's work was groundbreaking because it moved from a speculative study of diseases to a descriptive study of pathologies, which in turn was based on a theoretical study of bodies and organs. He believed that every disease had a cause, and that the point of cure was to remove the cause. This was a significant shift from the prevailing medical models of his time, which were often based on the works of Galen and Vesalius, and was influenced by the anatomical discoveries of his day.

Morgagni was a professor of medicine at the University of Bologna, and was later appointed as professor of medicine at the University of Padua in 1735. His high reputation was due to his anatomical studies of cadavers, particularly his examination of the liver. He developed a systematic approach to pathology, which included the classification of diseases and the study of their causative factors. His work was originally published in Latin, but it was later translated into Italian and French.

Morgagni's work had a profound impact on medical practice and education, and it is considered a seminal work in the field of medicine. His approach to pathology was based on a thorough study of cadavers, which provided a solid foundation for the field of pathology. He was a pioneer in the study of pathology, and his work continues to be studied and admired by medical professionals around the world.
MORGAN, D.—MORGAN, SIR H.

with the scalpel), his precision, his exhaustiveness, and his freedom from bias, are his essentially modern or scientific qualities; his scholarship and high consideration for classical and foreign work, his sense of practical ends (or his common sense), and the breadth of his interests, set him apart. Wherever his medical science had become largely technical or mechanical. His treatment was the commencement of the era of steady or cumulative progress in pathology and in practical medicine. Symptoms from that time ceased to be of mere incidental interest, for the first time in the medical history of the world. He defined disease in a way which a disease; on the other hand, they began to be viewed as “the cry of the suffering organs;” and it became possible to develop a theory of the natural history of the various organs, in a way that is essentially scientific.

A biography of Morgan by Mosca was published at Naples in 1768. His life may also be read in A. Fabrioni's Vitae illustr. Italer., and a convenient abridgment of Fabrioni's memoir will be found prefixed to Tissot's edition of the De sedibus, etc. Edition of his works was published at Venice in 5 vols. folio, in 1765.

MORGAN, DANIEL (1736-1802), American soldier, was born in Hunterdon county, New Jersey, in the winter of 1736, of Welsh ancestry. In 1753 he removed to Virginia. In June 1775, soon after the outbreak of the War of Independence, he was commissioned a captain of Virginia riflemen, and he marched his company to Boston in 21 days. In the winter of 1775 he accompanied General George Arnold to Canada. In the spring he joined General Gates on Quebec (Dec. 31) and his riflemen penetrated well into the city, where he was hemmed in and was forced to surrender. On the 7th of August 1776 he was discharged on parole; on the 12th of November he was commissioned colonel of the 11th Virginia; and soon afterwards he was released from his parole. In the summer of 1777 he was engaged in minor skirmishes in New Jersey, and early in September joined General Horatio Gates, then engaged in the campaign against General Burgoyne. At the first battle of Saratoga (Sept. 19) he was, until Arnold's arrival late in the day, the ranking officer on the field; and in the second battle (Oct. 7) also took a prominent part. Morgan rejoined Washington in November near Philadelphia. In March 1779 he was commissioned by Congress colonel of the 7th Virginia; but in July, suffering from poor health and disapproved because Congress did not advance him further in rank, he resigned from the army and retired to Virginia. After the battle of Camden, however, he joined Gates (then in command in the South) at Hillsborough, North Carolina, and on the 1st of October took command of a corps. On the 13th of the same month Congress tardily raised him to the rank of brigadier-general. In January 1781 Cornwallis and Tarleton attempted to entrap him, but at the Cowpens (Jan. 17) he defeated Tarleton and then escaped from Cornwallis into North Carolina. Apparently Morgan suggested to Greene (who had superseded Gates) that general's plan of battle at Guilford Court House on the 15th of March. In December 1783 he was commissioned major-general of Virginia militia, and in November 1794 commanded troops sent to suppress the Whisky Insurrection in western Pennsylvania. He was a Federalist representative in Congress in 1797-1799, and died in Winchester, Virginia, on the 6th of July 1802. See James Graham, The Life of General Daniel Morgan of the Virginia Line (New York, 1856); and Rebecca McConkey, The Hero of Cowpens (rev. ed., New York, 1885).

MORGAN, EDWIN DENNISON (1811-1883), American merchant and philanthropist, one of the “war governors” of New York state, was born in Washington, Berkshire county, Massachusetts, on the 8th of February 1811. He was first a clerk and then a partner in his uncle's store at Hartford, Connecticut, and became head of the New York firm of E. D. Morgan & Co. (formed in 1847). He engaged in politics, first as a Whig and then as a Republican. In 1849 he was elected president of the Board of Aldermen of New York City; he was a member of the state senate in 1850-1853 and procured the passage of the bill providing for the establishment of Central Park in New York City; in 1855-1858 he was state commissioner of immigration; from 1859 to 1863 he was governor of New York, being the first Republican executive of the state; in 1863-1866 he was United States senator from New York. He died in New York City on the 14th of February 1863. Morgan was one of the founders of the Republican party, and was chairman of the National Republican Committee in 1856-1864 and in 1872. He was one of the most efficient and able of the war governors; even before the outbreak of the Civil War he did much to prepare the state government for it, and from September 1861 to January 1863 he was in command of the military department of New York, with the rank of major-general of volunteers. He was a liberal donor to Union Theological Seminary, Williams College and other institutions. His collection of paintings and sculpture, much of which had long been loaned to the Metropolitan Museum, was sold in January 1886.

MORGAN, SIR HENRY (c. 1655-1688), Welsh buccaneer, and lieutenant-governor of Jamaica, was the eldest son of Robert Morgan of Llanhymny in Glamorganshire. He is said to have been kidnapped as a boy at Bristol and sold as a slave at Barbadoes, whence making his way to Jamaica, and is possibly to be identified with the Captain Morgan who accompanied the expedition of John Morris and Jackman when Vildemos, Trujillo and Granada were taken. In 1666 he commanded a ship in Edward Mansfield's expedition which seized the island of Providence or Santa Catalina, and when Mansfield was captured and killed by the Spaniards shortly afterwards Morgan was chosen by the buccaneers as their “admiral.” In 1668 he was commissioned by Sir Thomas Modyford, the governor of Jamaica, to capture some Spanish prisoners, in order to discover details of the threatened attack on Jamaica; and collecting ten ships with 500 men south of Cuba, he landed and marched to Puerto Principe, which he took and pillaged; and afterwards accomplished the extraordinary feat of taking by storm the fortified and well-garrisoned town of Porto Bello on the mainland. The governor of Panama, astonished at this daring adventure, in vain attempted to drive out the invaders, and finally Morgan consented to evacuate the place on the payment of a large ransom. These exploits had considerably exceeded the terms of Morgan's commission and had been accompanied by frightful cruelties and excesses; but the governor endeavoured to cover the whole under the necessity of allowing the English a free hand to attack the Spaniards whenever possible. Morgan was almost immediately entrusted with another expedition by Modyford against the Spaniards, and proceeded to ravage the coast of Cuba. In January 1669 the largest of his ships was blown up accidentally in the course of a caravel on board, Morgan and his officers narrowly escaping destruction. In March he sacked Maracaibo, and afterwards Gibraltar. Returning to Maracaibo, he found three Spanish ships waiting to intercept him; but these he destroyed or captured, recovered a considerable amount of treasure from one which had sunk, exacted a heavy ransom as the price of his evacuating the place, and finally by an ingenious stratagem eluded the enemy's guns altogether and escaped in safety. On his return to Jamaica he was again reproved, but not punished by Modyford. The Spaniards on their side were moreover acting in the same way, and a new commission was given to Morgan, as commander-in-chief of all the ships of war in Jamaica, to levy war on the Spaniards and destroy their ships and stores, the booty gained in the expedition being the only pay. Accordingly, after ravaging the coast of Cuba and the mainland, Morgan determined on an expedition to Panama. He recaptured the island of Santa Catalina on the 15th of December 1670, and on the 27th gained possession of the castle of Chagres, killing 300 of the garrison. Then with 1400 men he ascended the Chagres river, and after overcoming perils and obstacles of all kinds he appeared before Panama on the 18th of January 1671, defeated a much larger force than his own, and took the city. The fame of this brilliant exploit was, however, again obscured by abominable scenes of cruelty and debauchery, during which a gallon containing a considerable part of the booty escaped. Moreover, on returning to Chagres the members of the expedition found themselves cheated of their fair share of the spoil1 while Morgan escaped with a

XVIII. 27
few ships to Jamaica, leaving the rest to get home as best they could. On his return he received the thanks of the governor and council; but meanwhile on the 8th of July, 1760, a treaty had been signed between Spain and England, and both Modyford and Morgan were ordered home under arrest to answer for their conduct. Morgan, however, soon succeeded in gaining the king's favour, and in the autumn of 1674 he was appointed lieutenant-governor of Jamaica and was knighted, leaving England in December. After such a career as his it is not surprising that Morgan's conduct as a responsible official of the government was not very creditable. He was charged by Lord Vaughan, afterwards earl of Carbery, the governor, soon after his appointment, of persisting in encouraging privateering; he intrigued against his colleagues and successive governors of Jamaica, with the hope of superseding them; raised fictitious dissensions; and supported the outrageous conduct of his brother, Captain Charles Morgan, a terrible ruffian, and his kinsman, Colonel Byndos, taking part in their brawl and drunken orgies. He was finally, on the 12th of October 1683, suspended in Jamaica from all his employments; a general conclusion was confirmed by the government at home after hearing Morgan's defence, but he was restored to his place in the council on the 18th of July 1688, shortly before his death, which took place in August.

See A. O. Exquemelin (one of Morgan's buccaneers), Buccaneers of America (1864, reprinted in 1891); A. Morgan, History of the Family of Morgan (1901).

MORGAN, JOHN HUNT (1825-1864), American Confederate soldier, was born in Huntsville, Alabama, on the 1st of June 1825, and was brought up on a farm near Lexington, Kentucky, to which his parents removed in 1830. In the Mexican War he was a first lieutenant of a Kentucky cavalry regiment. On the outbreak of the Civil War he was captain of the Lexington Rifles (organized in 1857); in September 1861 he succeeded in getting out of Lexington the company's arms after the issue of the order for the disarming of the state guard, and late in the same month reached the Confederate camp at Woodsonville on the Green river. He proved himself an able scout, and was made captain of a cavalry company and commander of a cavalry squadron, including two other companies which in February 1862, with General A. S. Johnston's other forces, withdrew from Kentucky to Corinth, Mississippi. He was commissioned a colonel after the battle of Shiloh, and in July 1862, starting from eastern Tennessee, made the first of his famous raids. He routed a Federal force at Lebanon, destroyed much rolling stock and other railway property, and threatened Louisville and Cincinnati. In August and September he took part in General Bragg's invasion of Kentucky, and again threatened Ohio. In December he defeated the Union garrison at Huntsville, Tennessee, taking prisoners, valuable stores, and many cattle; he was commissioned brigadier-general for this success; and soon afterward again raided Kentucky. To cover Bragg's movement from Tullahoma to Chattanooga Morgan made, in July 1863, his famous raid into Indiana and Ohio. Bragg had instructed him to confine himself to Kentucky, but Morgan hoped to gain recruits in Indiana. On his arrival at Indianapolis, where opposition to the war was strong, with 2400 men he crossed the Cumberland and captured Bucksville, Kentucky, on the 2nd of July; on the 5th captured a garrison at Lebanon; and on the 13th entered Ohio near Harrison. The regular cavalry, under Generals E. H. Hobson and James M. Shackelford, was now close behind him, and his way was beset by quickly gathering militia. He marched through the suburbs of Cincinnati on the night of the 13th and on the 18th got to Portland, near Buffington Island, where he attempted to cross on the next day; but gunboats and steamers prevented him. In a sharp battle he lost 600 or more men. As many more surrendered soon afterwards, and about 300 crossed the river. On the 26th he surrendered to General Shackelford at New Lisbon. He was imprisoned with 70 of his men in the penitentiary at Columbus, from which on the night of the 27th of November he and six of his companions escaped by a tunnel they had dug. In the spring of 1864 he was put in virtual command of the Department of South-western Virginia, which included eastern Tennessee, and late in August he took command at Jonesboro, Georgia. On the 4th of September he was shot in a garden in Greenville, Tennessee, having been betrayed, it appears, to the Federals. Morgan had an excellent eye for topographical details, and by the swiftness of his movements and his sudden blows kept Kentucky in continual alarm. His lieutenant, Basil W. Duke, says that his force at no time reached 4000, but that it "killed and wounded nearly as many of the enemy and captured more than 15,000."

See Basil W. Duke, History of Morgan's Cavalry (Cincinnati, 1867).

MORGAN, JOHN PIERPONT (1837-1913), American financier and banker, was born in Hartford, Connecticut, on the 17th of April 1837, a son of Junius Spencer Morgan (1813-1890), who was a partner of George Peabody and the founder of the house of J. S. Morgan & Co. in London. He was educated at the English High School in Boston and at the University of Göttingen. In 1857-1860 he worked in the New York banking house of Duncan, Sherman & Co.; from 1860 to 1864 he was agent and attorney in New York for George Peabody & Co. of London, and Morgan, Grenfell & Co., for its successful bond issues of which he became head; in 1864-1872 he was a member of the firm of Dabney, Morgan & Co.; and in 1871 he entered the firm of Drexel, Morgan & Co., in which he was associated with Anthony J. Drexel, of Philadelphia, upon whose death in 1893 he became senior partner. In 1895 the firm became J. P. Morgan & Co. Closely associated with Drexel & Co. of Philadelphia, Morgan, Harjes & Co. (successors to Drexel, Harjes & Co.) of Paris, and Morgan, Grenfell & Co. (before 1910 J. S. Morgan & Co.) of London, it became, largely owing to Mr Morgan's ability, one of the most powerful banking houses in the world. It carried through the formation of the United States Steel Corporation (which took over the business of Andrew Carnegie and others), harmonized the coal and railway interests of Pennsylvania, and purchased the Leyland line of Atlantic steamships and other British lines in 1902, thus effecting an Atlantic shipping "combine" (See Steamship Lines) and, it, the banking house which has succeeded it, reorganized the following railways: Albany & Susquehanna (1869); the Chesapeake & Ohio, and the Cleveland, Cincinnati, Chicago & St Louis (1888); the Erie and the Reading (1893); the New York & New England (1896); the Northern Pacific (1897); the Baltimore & Ohio (1898), &c.; and in 1895 it supplied the United States government with $62,000,000 in gold to float a bond issue and restore the treasury surplus of $100,000,000. Mr Pierpont Morgan was a prominent member of the Protestant Episcopal Church; an enthusiastic yachtsman, whose "Columbia" defeated the "Shamrock" in 1899 and 1901 for the "America's" cup; a notable collector of books, pictures, and other art objects, many loaned or given to the Metropolitan Museum of Art (of which he was president), and many housed in his London house and in his private library on 36th Street, near Madison Avenue, New York City; and a generous benefactor of the American Museum of Natural History, the Corning Art Museum of Corning, New York; of the Carnegie Institute of Washington; and of the Lending Library of Harvard University (especially its medical school), the Lying-in Hospital of the city of New York and the New York trade schools.

MORGAN, LEWIS HENRY (1818-1885), American ethnologist, was born near Aurora, New York, on the 21st of November 1818. He graduated in 1840 at Union College, then studied law, was admitted to the bar, and practised his profession with success at Rochester, New York. Soon after leaving college Morgan went among the Iroquois, living as far as he could their life and studying their social organization. In October 1847 he was formally adopted into the Hawk gens of the Seneca tribe, and received the name "Ta-ya-da-wah-kugh." The fruit of his researches was The League of the Iroquois (1852; new ed. 1904), which, says J. W. Powell, "was the first scientific account of an Indian tribe ever given to the world." The success of the book encouraged him to further research, resulting in his Systems of Consanguinity and Affinity of the Human Family (1869). In 1877 he added to his reputation by publishing
Ancient Society, or Researches in the Lines of Human Progress from Savagery, through Barbarism, to Civilization, in which he divided the progress of culture into seven stages—"lower savagery," "middle savagery," "upper savagery," "lower barbarism," "middle barbarism" and "upper barbarism," and "civilization." The book was in four parts, dealing with (1) the growth of intelligence through inventions and discoveries; (2) the growth of the idea of government; (3) the growth of the idea of the family; and (4) the growth of the idea of property. Morgan was a member of the New York assembly in 1861 and of the New York senate in 1868-1869. In 1880 he was president of the American Association for the Advancement of Science. He died in Rochester, New York, on the 17th of December 1881. In addition to the works above mentioned and many magazine articles, he published The American Beaver and his Works (1868) and Houses and House-life of the American Aborigines (1881).

MORGAN, SYDNEY, Lady (c. 1783–1850). British authoress, daughter of Robert Owenston, an Irish actor, was born in 1783 in Dublin. She was one of the most vivd and hotly discussed literary figures of her generation. She began her career with a precocious volume of poems. She collected Irish tunes, for which she composed the words, thus setting a fashion adopted with signal success by Tom Moore. Her St Clair (1804), a novel of ill-judged marriage, ill-starred love, and impassioned nature-worship, in which the influence of Goethe and Rousseau was apparent, at once attracted attention. Another novel, The Novice of St Dominick (1806), was also praised for its qualities of imagination and description. But the book which made her reputation and brought her name into warm controversy was The Wild Irish Girl (1806), in which she appeared as the ardent champion of her native country, a politician rather than a novelist, extolling the beauty of Irish scenery, the richness of the natural wealth of Ireland, and the noble traditions of its early history. She was known in Catholic and Liberal circles by the name of her first marriage, "Maria Lisbona." Precocious Fringes followed in 1807. Miss Owenston entered the household of the marquess of Abercorn, and in 1812, persuaded by Lady Abercorn, she married the surgeon to the household, Thomas Charles Morgan, afterwards knighted; but books still continued to flow from her facile pen. In 1814 she produced her best novel, O'Donnell. She was at her best in her descriptions of the poorer classes, of whom she had a thorough knowledge. Her elaborate study (1817) of France under the Bourbon restoration was attacked with outrageous fury in the Quarterly, the authoress being accused of Jacobinism, falsehood, licentiousness and impiety. She took her revenge indirectly in the novel of Florence Macarthy (1818), in which a Quarterly reviewer, Con Crawley, is insulted with supreme feminine ingenuity. Italy, a companion work to her France, was published in 1821; Lord Byron bears testimony to the justness of its pictures of life. The results of Italian historical studies were published in Life and Times of Salvador Rosa (1832). Then she turned again to Irish manners and politics with a matter-of-fact book on Absenteeism (1835), and a romantic novel, The O'Brien and the O'Flahertys (1837). From Lord Melbourne Lady Morgan obtained a pension of £100. During the later years of her long life she published The Book of the Boudoir (1820), Dramatic Scenes from Real Life (1833), The Princess (1835), Woman and her Master (1840), The Book without a Name (1841), Passages from my Autobiography (1850). She died on the 14th of April 1859.

Her autobiography and many interesting letters were edited with a memoir by W. Hepworth Dixon in 1862. MORGAN, THOMAS (d. 1743). English deist, of Welsh extraction, became an independent minister, but soon after 1720 lost his position owing to the growing unorthodoxy of his views. He took up medicine and became a freethinker, though he describes himself as a Christian deist. He was an energetic controversialist. Among his works are Philosophical Principles of Medicine (1725); Collection of Tracts (1726), essays dealing with the Trinitarian controversy; The Moral Philosopher (1737), a dialogue between a Christian Jew, Theophanus, and a Christian deist, Philalethes. He died on the 14th of January 1742/3.

MORGANATIC MARRIAGE, a form of marriage properly peculiar to the German peoples, but also found in the royal families of other European countries. It is one in which the contracting parties are not by birth of equal status or rank (ebenbürtig), and under which the wife, if not ebenbürtig, does not take the rank of her husband, and the children, whether it be the wife or husband that is of lower rank, have no right of succession to the dignities, fees or entailed property of the parent of higher rank. This equality by birth was formerly throughout Germany the necessary condition to a complete and perfect marriage, but it is now only applicable to members of reigning houses or of the higher nobility (hoher Adel), and it is thus of force among the "mediatized" princes of the German Empire. In the constitution of the various states, and in the "house laws" (Hausgesetze) of the reigning families, the rules are laid down as to what constitutes ebenbürtigkeit. Generally it may be said that members of a present or former reigning house, either in Germany or Europe, would be recognised as ebenbürtig, but a former morganatic marriage would be taken as destroying the qualification. In Great Britain the regulations as to the marriages of members of the royal family are contained in the Royal Marriage Act 1772 (see MARRIAGE). The term "morganatic marriage" is applied generally to any marriage of a person of royal blood with one of inferior rank. The origin of the term, in medieval Latin matrimonium ad morganaticam, is usually taken to refer to the Morgengabe, i.e. the morning gift, made by a husband to his wife on marriage. The German name is Ehe zur linken Hand (marriage by the left hand, whence the phrase a "left-handed marriage"), the husband of such marriage ceremonies giving the left instead of the right hand to the bride. Such marriages are recognized as fully binding by the Church, and the children are legitimate, and no other marriage can take place during the lifetime of the contracting parties.

MORGANTOWN, a city and the county-seat of Monongalia county, West Virginia, U.S.A., on the Monongahela river, about 50 m. S.E. of Wheeling. Pop. (1890), 1011; (1900), 1895; (1920 census), 9135. The city is served by the Baltimore & Ohio and the Morgantown & Kingwood railways, and by several steamboat lines, the Monongahela being navigable to Fairmont, about 25 m. above Morgantown. Morgantown is the seat of the West Virginia University (co-educational), formed from the Monongalia Academy (incorporated, 1814) and the Woodburn Female Seminary (incorporated, 1858), and chartered in 1867 as the Agricultural College of West Virginia; in 1868 the present name was adopted. In 1908 the university had 80 instructors and 1534 students. Coal, glass-sand and limestone are found in the vicinity of Morgantown. The first settlement here was made about 1768 by the brothers David and Zachwell Morgan, and was named in honor of the latter. It was incorporated as Morgan's Town in 1785; and in 1905 a city charter was granted to it after the annexation of Greenmont (pop. 1900, 349), Seneca (pop. 1900, 723), and South Morgantown (pop. 1900, 405).

MORGARTEN, the name of the pasture slopes that descend westwards to the south end of the lake of Aegeri in the Swiss canton of Zug, about 2 m. by road from the Sattel station on the railway line from Schwyz to Zürich. It was at the foot of these slopes and on the shore of the lake that the small Swiss force defeated the large Austrian army, advancing from Zug on Schwyz, on the 15th of November 1315, and so laid the foundations of Swiss liberty. As the lake has shrunk, the exact site of the battle has been disputed. It seems most probable that it took place near the Haselmatt Chapel, in the territory of Zug, where is the official monument, but some hold that the real site was in Schwyz territory, near the old tower and battle chapel of Schornen, in the gorge between the lake and Sattel.

The original accounts of the battle are collected in part iii. (1884) of
the Mitteilungen of the Historical Society of Schwyz. See also the careful study in K. Bürki’s Etn Denkmal am Morgarten wo ist sein Platz? (Zur, 1895).

MORGEN, a unit of measurement of land in Holland and the Dutch colonies, and hence still current in South Africa, equivalent to about 2 acres. It is also used in Prussia, Norway and Denmark, where it equals about two-thirds of an acre. The word is usually taken to be the same as the German and Dutch word for “morning,” the area of a “morgen” being equal to that covered by a morning’s ploughing.

MORGENH, RAFFAELLO SANZIO (1578-1833), Italian engraver, was born at Naples on the 10th of June 1788. He received his earliest instructions from his father, himself an engraver; but, in order to be initiated more fully in the art, he was afterwards placed as a pupil under the celebrated Volpato. He assisted this master in engraving the famous pictures of Raphael in the Vatican, and the print which represents the miracle of Bolsena is inscribed with his name. He married Volpato’s daughter, and, being invited to Florence to engrave the masterpieces of the Florentine Gallery, he removed thither with his wife in 1782. His reputation now became so great as to induce the artists of Florence to recommend him to the grand duke as a fit person to engrave the “Last Supper” of Leonardo da Vinci; apart, however, from the diaplated state of the picture itself, the drawing made for Morgenh was unprofitable of the original, and the print, in consequence, although an admirable production, fails to convey a correct idea of the style and merit of Leonardo. Morgenh’s fame, however, soon extended over Europe; and the Institute of France, as a mark of their admiration of his talents, elected him an associate in 1823. In 1812 Napoleon invited him to Paris and paid him the most flattering attentions. He died at Florence on the 8th of April 1833.

A list of the artist’s works, published at Florence in 1810, comprised 200 compositions; the number was afterwards considerably increased, amongst the most remarkable, besides those already mentioned, may be noticed the Transfiguration from Raphael, a Magdalen from Murillo, a Head of the Saviour from da Vinci, the Car of Aurora from Guido, the Hours and the Repose in Egypt from Poussin, the Prise of Dianas from Domenichino, the Monuments of Clement XIII. from Canova, Theseus vanquishing the Minotaur, Francesco Monaco after Van Dyck, portraits of Dante, Petrarch, Ariosto, Tasso, and a number of other eminent men. His prints have however maintained the reputation which they enjoyed during the artist’s lifetime. Though carefully and delicately executed, they are somewhat mechanical and wanting in force and spirit.

MORHIER, SIMON (d. c. 1450), provost of Paris during the English occupation in the 15th century, was seigneur of Gilles, near Nogent-le-Roi, in the Chartain country. Being a member of the duke of Burgundy’s party, he was appointed provost at Paris by John, duke of Bedford, on the 1st of December 1422. He was taken at prisoner at the siege of Montargis in 1427, and again at the battle of Rouvrai in 1429; but in September of the latter year he repulsed Joan of Arc’s attack upon Paris. After a campaign in Cotentin in 1435, he was once more taken prisoner at the bridge of Charenton in 1436. Remaining faithful to the English party, he became captain of Dreux, a councillor of Henry VI., and treasurer of France and Normandy. He assisted in the defence of Meaux (1439), of Crel and of Pontoise (1441), and must have died between 1450 and 1456. See the Nouvelle biographie générale, vol. xxxvi.; and a note on Simon Morhier in the memoirs of the Antiquarian Society of France, vol. xxv.

MORHOF, DANIEL GEORG (1639-1693), German man of letters, was born at Wismar on the 6th of February 1639. He first studied jurisprudence and then HIERO HUMANITATUM at the university of Rostock, where his elegant Latin versification procured for him in 1660 the chair of poetry. In 1665 he went to the university of Kiel as professor of eloquence and poetry; this chair he exchanged for that of history in 1672. He died at Lübeck on the 30th of July 1691. Of his numerous writings the most important are Unterricht von der deutschen Sprache und Poesie (1682; 3rd ed., 1718), the first attempt in Germany at a systematic survey of European literature, and Polyhistor, sive de auctorum notitia et rerum commentaxis (Lübeck, 1688, not completed till 1707; 4th ed., 1747), a kind of encyclopaedia of the knowledge and learning of his time.

See Eymer, Morhof und sein Polyhistor (in the Xenia Austriaca, Vienna, 1843), and biography by K. v. Lilienron in Allgemeine Biographie (1885).

MORIAH, an obscure place-name of ancient Palestine with apparently two distinct connotations. (1) A land entirely unknown, on a mountain in which Abraham offered Isaac (Gen. xxii. 2). The text is probably corrupt; some have suggested “land of the Amorites,” others “land of Midian.” The etymology of the word is equally obscure. Traditionally, of course, “the land of Moriah” is identified with the site of the Temple at Jerusalem, except by the Samaritans and a few western scholars (such as Dean Stanley) who accept their belief that the mountain was Gerizim. (2) The upper part of the hill of Ophel, the threshing floor of Araunah, upon which Solomon erected the Temple, is once called Mount Moriah (2 Chron. iii. 1). Whether this name be derived from the corruption in Genesis or not cannot be definitely decided; it very likely is. The testimony of Josephus, who often names the temple hill “Moriah,” is of course not original, and of no weight.

MORIER, JAMES (1789-1844), English traveller and author, was born in 1780. Through the influence of his uncle, Admiral William Waldegrave, Baron Radstock, he entered the diplomatic service; and as secretary to Lord Elgin followed the grand vizier in the Egypt campaign, and in consequence of his Eastern experiences was published in 1812, under the title A Journey through Persia, Armenia and Asia Minor to Constantinople in 1808-9. From 1810 to 1816 he was the British representative at the court of Persia, and after his return he published A Second Journey through Persia and Constantinople between the years 1810 and 1816. His knowledge of Eastern life and manners he also turned to account in the composition of several entertaining romances. The most popular of these were The Adventures of Hajji Baba of Ispahan (1824), The Adventures of Hajji Baba of Isfahan in England (1828), Zohrab the Hostage (1832), and Ayesha the Maid of Kars (1834). Morier died at Brighton on the 23rd of March 1840.

MORIER, SIR ROBERT BURNETT DAVID (1826-1853), British diplomatist, was born at Paris on the 31st of March 1826. He was descended from a family of diplomatists of Huguenot origin, the best known of whom were his father David, consul-general for France and minister at Bern, and his uncle James, the author of The Adventures of Hajji Baba. After a somewhat defective private education he came up to Balliol College, Oxford, but he was removed from the university of Oxford by his father, under whose influence his brilliant but wayward mind was placed on the discipline of which it stood in need. The relation of tutor and pupil developed into a friendship of rare warmth. Writing towards the close of his life, Jowett, who inspired more devoted friendships than any man of his time, spoke of Morier as his kindest and best friend for forty-five years. On leaving Oxford, Morier at first obtained an appointment in the Education Department, but resigned in 1852, and in the following year became attached at Vienna. In the succeeding years he was attached in turn to almost every court in Germany. Restless in temperament and unconventional in method, he plunged into the vortex of German politics to a degree that did not always accord with the traditions of diplomacy. The most important years of his career in Germany were from 1866 to 1871, when he was secretary of legation at Darmstadt. Here he became a trusted adviser of the crown princess, and through her acquired an intimate friendship with the crown prince (afterwards the emperor Frederick III.), whose antagonism to Bismarck’s reactionary policy met with cordial support from Morier’s sturdy Liberalism. Bismarck, already jealous of British influence at court, honoured Morier with a hatred not lessened by the fact that Morier’s knowledge of German politics was unrivalled outside Germany. On leaving Darmstadt, Morier became chargé d’affaires, first at Stuttgart

1 Some of the sects transfer the scene of the sacrifice to the “Chapel of Abraham” in the precincts of the Holy Sepulchre Church.
and then at Munich, and in 1876 was appointed minister at Lisbon. From 1881 to 1884 he was minister at Madrid. In December 1884 he became ambassador at St Petersburg, and almost immediately had to face the alarming situation created by the Russian advance to Penjdeh. Thanks to his efforts, a war that at one moment seemed inevitable was averted. His great popularity in the Russian court contributed towards a well-marked improvement in the relations between the two countries. Bismarck took alarm at the lessening influence of Germany over Russia, and tried to procure Morier's downfall. The Kölnerische Zeitung declared in December 1888 that Morier had made use of his position at Darmstadt during the Franco-German War to betray the movements of the German troops to Marshal Bazaine. The authority for this charge was an alleged declaration made by Bazaine to the German military attaché at Madrid. Bazaine had died in September, but Morier had heard rumours in July of the charge brought against him, and had procured from Bazaine a written denial, which he now published in The Times. Apart from this, it was clearly shown that Morier could not have transmitted the information by the alleged date, and that Bazaine, according to the testimony of his own books and of other officers, received the information in question by reports from the front. As a matter of fact, Morier was an ardent champion of the German cause. His correspondence with Jowett shows the latter vailing, indeed, to convince his friend that the French were in the right. Public opinion everywhere, except in the German Conservative press, attributed the charge to political motives. Morier's falling health caused him, at his own request, to be appointed Lord Dufferin's successor at Rome in 1891; but it was felt that he could not be spared from St Petersburg, and there he remained till forced to find a milder climate. It was then too late, and he died at Montreux in Switzerland on the 6th of November 1893.

MORIKE, EDUARD FRIEDRICH (1804–1875), German poet, was born at Ludwigsburg on the 8th of September 1804. In 1834 he was appointed pastor of Kloversulzbach near Weinsberg, and in 1851 became professor of literature at the Katharinenschut in Stuttgart. This office he held until his retirement in 1866; but he continued to live at Stuttgart until his death on the 4th of June 1875. Morike is the most lyrically gifted of all the poets belonging to the so-called Swabian school which gathered around Ublen. His poems, Gedichte (1838; 2nd ed., 1866), are mostly lyrics, graceful in style, original in conception, often humorous, but expressed in simple and natural language. He also wrote a somewhat fantastic Idyle vom Bodensee, oder Fischer Martin und die Glockendiebe (1846; 2nd ed., 1856), and published a collection of hymns, odes, elegies and idylls of the Greeks and Romans, entitled Klassische Blumenlese (1848), and several novels and narratives, among the former Maler Nolten (1832; 6th ed., 1901), which enjoyed great popularity.

Morike's Gesammelte Schriften were first published in 4 vols. (in 1878); the most recent editions are those edited by K. Fischer (6 vols., 1905), and the Volkgsausgabe, published by Gössen (4 vols., 1905). Selections from his literary remains were published by R. Krauss in Eduard Morike als Gelehrtenstischer (1895), and his correspondence with Hermann Leberecht Richter by Theodor Naude (1885–1891); an edition of Morike's Ausgewählte Briefe, in 2 vols., appeared 1903–1904. See F. Notter, Eduard Morike (1875); and H. Fischer, Eduard Morike (1891); K. Fischer, E. Morike (1901); H. Mayne, E. Morike (1901); K. Fischer, Morikes bänkische Schriften und dichitische Schöpfungen (1903).

MORILLON, a name commonly given to fowlers to the female or immature male of the Golden-Eye (anat. gansis), the Clangula glaucio of modern ornithology, under the belief—which still very generally obtained among them, as it once did among naturalists—that they formed a distinct species of duck. The mistake no doubt originated in, and is partly excused by, the facts that the birds called Morillons were often of opposite sexes, and differed greatly from the adult male Golden-Eye, whose full and beautiful plumage is not assumed until the second year. The word is used in French in precisely the same form, but it is in that language applied to the Tufted Duck, Fuligula cristata, and is derived, according to Littre, from mor, signifying black.

Morin, Jean (Latinized Joannes Morinus) (1501–1569), French theologian, was born in 1501 at Blois, of Protestant parents. He learned Latin and Greek at Rochelle, and continued his studies at Leiden, subsequently removing to Paris. His conversion to the Roman Church is ascribed to Cardinal du Perron. In 1658 he became Dean of the Sorbonne of the Oratory, and the next year took the course took priest's orders. In 1653 he visited England in the train of Henrietta Maria; in 1650 he was at Rome, on the invitation of Cardinal Barberini, and was received with special favour by Pope Urban VIII. He was, however, soon recalled to Paris by Richelieu, and the rest of his life was spent in incessant literary labour. The Histoire de la délivrance de l'église chrétienne par l'emp. Constantin, et de la grande et souveraine-temporelle donnée à l'église romaine par les rois de France (1650) gave great offence at Rome, and a Déclaration (1654), directed against faults in the administration of the Oratory, was strictly suppressed. So, too, his great work on penance gave equal offence to the Jesuits and to Port-Royal, and even after his death, in 1659, the polemical vehemence of his Exercitatio biblesicae, and the exaggeration of his assertion "apud neotericos Hsereticae scriptingur unum, non superum, non solum medulam et radicem textus laceritam," long led Protestants to treat his valuable contributions to the history of the Hebrew text as a mere utterance of Popish prejudice.

Morin was a voluminous and prolific writer on ecclesiastical antiquities. His principal works in this field are Commentarius historicus de disciplina in administratione sacramentorum poenitentiae XIII, primit. secul. in ecc. occid. et haesuerit in oris. observat. (1651), and Comm. de saeculis ecclesiast. ovariorum biblicarum et recentiorum latinos, graecos, syros et babylonios (1655), which expresses those irreconcilable views on the subject of ordination which recommended Morin to Urban VIII. The literary correspondence of Morin appeared in 1682 under the title of Antiquitates ecclesiast orientalis (edited by R. Simon).

Morin's chief fame, however, rests on his biblical and critical work. By his edito princeps of the Samaritan Pentateuch and Targum, in the Paris Polyglott, he gave the first impulse in Europe to the study of this dialect, which he acquired without a teacher (framing a grammar for himself) by the study of MSS. then newly brought to Europe. Not unnaturally he formed a very exaggerated view of the value of the Samaritan tradition of the text (Exercitatio in utrumque Samaritanae Pentateuchum, 1651). A similar tone of exaggerated depreciation of the Massoretic Hebrew text, coloured by polemical bias against Protestantism, marks his greatest work, Supplements Exercit. (1660), in which, following in the footsteps of Cappellus, but with incomparably greater learning, he brings irrefragable arguments against the then current theory of the absolute integrity of the Hebrew text and the antiquity of the vowel points.

MORION (the French form of a word occurring in Spanish as morrion, It. morione, usually connected with the Sano. morro, top or crown of the head), a light round-shaped head-piece or helmet (q.v.). The chief characteristics are a brim, an upright comb running along the crown from back to front, and the absence of guards for the face, ears or neck. The brim was bent sharply at the front and back, and the piece was generally worn tilted backward so as to cover the neck. The lower part was a helmet-shaped headpiece with a flatter brim and no comb, were the typical infantry helmets of the 16th and early 17th centuries. It was sometimes worn unaccompanied by any body armour.

MORISCOS (i.e. little Moors), the name given to the Spanish Mahomedans who accepted baptism and their descendants. Many, if not most, of them were in reality of the same race as the Christians, and were descended from converts to Islam. Those Mahomedans who retained their religion under Christian rulers were known as Mudéjars, a word of Arabic origin which has been interpreted as meaning "those who remained" or "were left." Until the 15th century they were numerous, and enjoyed free exercise of their religion, which was secured to them by capitulations and treaties. Their number had been considerably diminished by the time of the conquest of Granada in 1492. By the terms of the capitulation of the city freedom of worship was secured to the Mahomedans. But the policy of the Catholic sovereigns, who desired to establish unity of faith
among their subjects, and the influence of the Church, soon led to violations of the treaty. The first Christian archbishop of Granada, Talavera, made some progress in converting the people peacefully. But at the end of 1490 Cardinal Jiménez insisted on adopting coercive measures. A rebellion ensued, and the Mahomedans were suppressed. Want of power, or other obstacles, delayed the final extinction of tolerated Mahomedanism in all parts of Spain, but by 1525 it was everywhere suppressed. The last remains of it were crushed in Valencia, where the Mahomedans were furiously attacked by the Christian peasantry during the great agrarian revolt known as the Germania, 1520–1521. As they were dependent on the protection of the landlords, the Mahomedans were docile tenants, and their competition weighed heavily on the Christians. The same quality of industry remained to the Moriscos, and excited the envy of their Christian fellow countrymen. The feelings with which they were regarded are admirably shown by Cervantes (who shared them to the full) in his "Conversation of the Two Dogs." In 1586 the government of Philip II. issued an edict, which ordered them to return all their Moorish ways of life and to give the children to be educated by Christian priors. The result was a rebellion in Granada, which was put down with great difficulty. The Moriscos were expelled from Granada and scattered over other parts of Spain. Many fled to Africa, where the more spirited among them took to piracy at Algiers and other ports. They still maintained relations with their kinsfolk in Spain, and the whole coast suffered from their incursions. The Moriscos entered into relations with other enemies of Spain, and notably, with France. Henry IV. included a plan for supporting a Morisco rebellion in the great scheme for the destruction of the Spanish monarchy, which he was about to put into execution when he was murdered on the 14th of May 1610. These intrigues were known to the Spanish government and inspired it with terror. The expulsion of the whole body of Moriscos was decided on in 1608, and the edict was published on the 22nd of September 1609. The expulsion was carried out with great cruelty. The number driven out has been variously estimated at 120,000 or at 3,000,000. In some known cases the expelled Moriscos suffered martyrdom in Africa as Christians. A few were left in Spain as domestic slaves, and some contrived to return in secret. Cases of crypto-Mahomedanism continued to come before the Inquisition till the 18th century.

MORISON, JAMES AUGUSTUS Cotter (1832–1888), British author, was born in London on the 20th of April 1832. His father, who had made a large fortune as the inventor and proprietor of "Morison's Pills," settled in Paris till his death in 1840, and Cotter Morison thus acquired not only an acquaintance with the French language, but a profound sympathy with France and French institutions. In later life he resided for some years in Paris, where his house was a meeting-place for eminent men of all shades of opinion. He was educated at Highgate grammar school and Lincoln College, Oxford. Here he fell under the influence of Macaulay, and was himself to some extent a little interested in history. It was perhaps to his self-consciousness that characterized his whole career. He also made the acquaintance of the leading English Positivists, to whose opinions he became an ardent convert. Yet he retained a strong sympathy with the Roman Catholic religion, and at one time spent several weeks in a Catholic monastery. One other great influence appears in the admirable Life of St Bernard, which he published in 1863—that of his friend Carlyle, to whom the work is dedicated, and with whose style it is strongly coloured. Meanwhile he had been a regular contributor, first to the Literary Gazette, edited by his friend John Morley, and then to the Saturday Review at its most brilliant epoch. In 1868 he published a pamphlet entitled Irish Grievances shortly stated. In 1878 he published a volume on Gibbon in the "Men of Letters" series, marked by sound judgment and wide reading. This he followed up in 1882 with his Macaulay in the same series. It exhibits, more clearly perhaps than any other of Morison's works, both his merits and his defects. Macaulay's bluff and strenuous character, his rhetorical style, his unphilosophical conception of history, were entirely out of harmony with Morison's prepossessions. Yet in his anxiety to do justice to his subject he steeped himself in Macaulay till his style often recalls that which he is censuring. His brief sketch, Mme de Maintenon: une étude (1885), and some magazine articles, were the only fruits of his labours in French history. Towards the close of his life he meditated a work showing the application of Positivist principles to conduct. Unfortunately, failing health compelled him to abandon the second or constructive part: the first, a brilliant piece of writing which attempts to show the ethical inadequacy of revealed religion and is marked in parts by much bitterness, was published in 1887 under the title of The Service of Man. He died in London on the 26th of February 1888.

MORITZ, KARL PHILIPP (1757–1793), German author, was born at Hamelin on the Weser on the 13th of September 1757, of humble parentage. After receiving a scanty schooling, he was apprenticed to a hat-maker, but was later enabled to study philosophy by Erfurt and Wittenberg and in 1777 became teacher in a school at Darmstadt. While on one of his itinerances in 1786 he became acquainted with Goethe, who interested himself in him. On his return, he was appointed professor of archaeology and aesthetics, at the academy of art in Berlin, and in this city he died on the 26th of June 1793. Of Moritz's writings on aesthetic, archaeological and philosophical subjects, the little treatise Über die bildende Nachahmung des Schönen (1878; reprinted 1888) and Die Göttlerlehre (1791; 10th ed., 1855, a reprint in Reclam's Universalbibliothek, 1878) are important; interesting, too, are the accounts of his travels, Reisen eines Deutschen in England (1788; repr. 1903; also trans. into Eng.) and Reisen eines Deutschen in Italien (3 vols., 1792–1793). As an author he is best known by his two novels, Anton Reiser (1785–1790; new ed. by L. Geiger, 1886) and Andreas Hartkopf (1786), which are mainly autobiographical.

See K. F. Klüsschberg, Einleitungen aus den zehn letzten Lebensjahren meines Freundes Anton Reiser (1794); Varnhagen von Ense, Denkwürdigkeiten (1832); and M. Dessay, Karl Philipp Moritz als Aesthetiker (1889).

MORLAIX, a town of western France, capital of an arrondissement in the department of Finistère, 37 m. E.N.E. of Brest on the railway to Rennes. Pop. (1906), 13,875. Morlaix lies between 4 and 5 m. from the English Channel in a narrow valley where two small streams unite to form the Dossen, the channel of which forms its port. Below the town the river widens into an estuary, the mouth of which is commanded by an old fortress, the Château du Taureau, built in 1542 to protect the town against the English. The railway from Paris to Brest crosses the valley on a striking two-storeyed viaduct some 200 ft. above the quays. Morlaix contains a considerable number of wooden houses of the 15th, 16th and 17th centuries. These have large covered courts, with huge open fireplaces and carved wooden staircases, supported on pillars, leading from the court to the upper storeys.

Morlaix has a sub-prefecture, tribunals of first instance and of commerce, a chamber of commerce, and colleges for boys and girls. The industries include the manufacture of tobacco occupying about 900 hands, tanning, brewing and the manufacture of casks, wooden shoes and candles; there is an active trade in grain, butter, oil-seeds, vegetables, leather, wax, honey and in horses and other livestock, which are exported by sea. The port, consisting of an outer tidal harbour and an inner basin, admits vessels drawing 17 ft. at spring tides and 12 ft. at neap tides.

Judging by the numerous coins found on the spot, the site of Morlaix was probably occupied in the time of the Romans. The counts of Leon held the lordship in the 12th century, but the dukes of Brittany disputed possession with them, and in 1187 Henry II. of England, guardian of Arthur of Brittany, made himself master of the town after a siege of several weeks. During the Hundred Years' War Morlaix was held by the French and the English in turn, and pillaged by the latter in 1522. Queen
Mary of Scots, on her way to be married to the dauphin, made solemn entry into Morlaix in 1548. The town having joined the League, the castle was taken by storm in the name of Henry IV, in 1594.

MORLAND, GEORGE (1753–1804), English painter of animals and rustic scenes, was born in London on the 26th of June 1753. His grandfather, George H. Morland, was a subject painter, three of whose popular pictures were engraved by Watson and Dawe in 1799. The son, H. R. Morland, father of George, was also an artist and engraver, and picture restorer, at one time a rich man, but later in reduced circumstances. His pictures of laundry-maids especially were very popular in their time, and were reproduced in mezzotint. They represented ladies of some importance who desired to be painted, according to the fashion of the day, engaged in domestic work. Morland's mother was a Frenchwoman, who possessed a small independent property of her own; she is believed to have been the Maria Morland who exhibited twice at the Royal Academy in 1785 and 1786, although some writers have stated that Maria Morland was not the mother, but one of the sisters of George Morland.

At a very early age Morland produced sketches of remarkable promise, exhibiting some at the Royal Academy in 1775, when he was but ten years old, and being longer exhibit at the French Society in 1776, and at the Society of Artists in 1777, and then sending again to the Royal Academy in 1778, 1779 and 1780. His very earliest work, however, was produced even before that tender age, as his father kept a drawing which the boy had executed when he was but four years old, representing a coach and horses and two footmen. He was a student at the Royal Academy in early youth, but only for a very short time. From the age of fourteen he was apprenticed to his father for seven years, and by means of his talent appears to have kept the family together. He had opportunities at this time of seeing some of the greatest artists of the day, and works by old masters, but even then a strange repugnance for educated society showed itself, and no persuasion, for example, could ever allure him within reach of the Angerstein gallery, where he would have been a welcome visitor. Before his apprenticeship came to an end, Romney offered to take Morland into his studio for three years, with a salary of £500 a year, but the offer was rejected, and as soon as his freedom came, he left his dull, respectable home, with its family circle forever behind, and moved to London in order to study painting, which has hardly a parallel in art biography. In 1785 he was in France, whither his fame had preceded him, and where he had no lack of commissions, and in the following year he married Anne, the sister of William Ward, the engraver, and settled down in High Street, Marylebone.

Mrs Morland was a beautiful and virtuous woman, and throughout the whole of her husband's profligate career was deeply attached to him. It was at this time that he painted the six pictures known as the Laetitia series, engraved by J. R. Smith, and, just preceding his marriage, four other didactic works, "The Idle and the Industrious Mechanic" and "The Idle Laundress and the Industrious Cottager," engraved by Blake, had been produced by him. Shortly after his marriage Morland resided at Pleasant Passage, Hampstead Road, and at that time his reputation was rapidly increasing, while he was the sole vendor of his own productions, his expenditure, although very extravagant, was not beyond his income. Soon, however, he moved to Warren Place, and there, although he was making a thousand a year by his pictures, he lived at such an expense that he began the series of financial difficulties which finally ruined him. His wild frolics about town, and the prodigal line of conduct upon which he had entered, resulted in a heavy accumulation of debt, but in 1789 he set himself to clear off his encumbrances, and did so in fifteen months. He then removed to Leicester Square, later to Tavistock Row, then to St Martin's Lane, and finally to Paddington, and was at that time at the very height of his reputation.

After moving to a larger house in Winchester Road, his financial position became so embarrassed that he had to fly from his creditors into Leicestershire, where he indulged to the full his delight in animal life. After a year, however, he returned to London and settled in Charlotte Street, when his difficulties increased, and time after time he has to obtain letters of licence, in order to avoid being arrested by his creditors. At last, however, he had to cross the water, and change his place of abode from time to time, keeping it as secret as possible, and we hear of him at Lambeth, at East Sheen, in the Minories, Kentish Town, Soho, Newington, Kennington Green and Hackney, while he had numerous adventures in eluding the attention of those who desired to capture him.

In 1790 he escaped to the Isle of Wight, and settled down for some time at Yarmouth, but returned to London at the end of the year, was arrested and sent to King's Bench prison, where he lived within the rules, occupying a small furnished house in St George's Fields, but keeping his exact residence a secret. In 1802 he was liberated, but in 1803 had to place himself in the custody of the Marshalsea, in order to avoid his creditors. Afterwards he visited Brighton and other places, and by his riotous living brought himself to such a state of health that fits of an apoplectic nature became frequent, and he was for a time paralysed. On the 19th of October 1804 he was arrested by a publican and conveyed to a sponging-house, where, in attempting to make a charge on a woman who could not be found, he was seized with a fit which proved the beginning of his end. He died on the 29th of the same month. His wife survived him only three days, the news of his death bringing on convulsive fits from which she died on the 2nd of November. Their remains were interred together in the burying-place of St James's Chapel.

The finest of his pictures were executed between 1790 and 1794, and amongst them his picture of the inside of a stable, in the National Gallery, may be reckoned as a masterpiece. His works deal with scenes in rustic and homely life, depicted with purity and simplicity, and show much direct and instinctive feeling for nature. His colouring is mellow, rich in tone, and vibrant in quality, but, with all their charm, his works reveal often signs of the haste with which they were painted and the carelessness with which they were drawn. He had a supreme power of observation and great executive skill, and he was able to select the vital constituents of a scene and depict even the least interesting of subjects with artistic grace and brilliant representation. His pictures are never crowded; the figures in them remarkably well contrasted, often cleverly grouped to conceal any inaccuracies of drawing, and to produce the effect of a very successful composition. As a painter of English scenes he takes the very highest position, and his work is marked by a spirit and a dash, always combined with broad, harmonious colouring. Many of his best works have been well rendered in mezzotint by J. R. Smith, W. Ward, P. Dawe, G. Keating, S. W. Reynolds and other engravers. He exhibited regularly at the Royal Academy from 1784 down to 1804, and few of his academy pictures can be identified owing to the inadequate description of them afforded by their titles.

Four biographies of him appeared shortly after his death, written by W. Collins (1805), F. W. Bladon (1806), J. Hassell (1806) and George Dawe (1807). Later biographies are those by Ralph W. Ward (1895), J. T. Smith (1898) and G. C. Pinto and R. H. Round (1904 and 1907).

MORLANWEZ, a town of Belgium in the province of Hainault, 15 m. E. of Mons. It lies in the centre of the coal-mines district and has extensive foundries and ironworks. Pop. (1904), 8200.

MORLANWEZ, BARONS AND EARLS OF. In 1599 William de Morley of Morley in Norfolk was summoned to parliament as a baron, and his son Robert (d. 1390) was a celebrated warrior, being largely responsible for the English victory at Sluys and fighting at Crécy. His descendant Robert, the 6th baron (d. 1443), had no sons, but he left a daughter Alianore, who married William Lovel (d. 1476), and Lovel was summoned to parliament as Lord Morley, ranking as the 7th holder of the title. He left a son Henry, who was killed in 1489, and Henry's heir was his sister Alice, the wife of Sir William Parker (d. 1510), hereditary marshal of Ireland. Their son Henry Parker (1476–1556) became the 10th baron, as he was summoned to the House of
MORLEY, G.—MORLEY, JOHN

840

Lords as Lord Morley in 1523. He was a man of literary attainments and translated some of the writings of Plutarch, Boccaccio, Petrarch, Seneca, Cicero and others into English. Most of these are only found in manuscript, but his Triumphs of Frances Petrarque was published a second time in 1887. His eldest son Henry (d. 1555) died during his father's lifetime, leaving a son Henry (d. 1577) who became 11th Baron Morley on his grandfather's death. His son Edward (d. 1618), one of the judges of Mary Queen of Scots, succeeded to the barony; and Edward's son and successor was William Parker, 4th Lord Montague (q.v.). The barony of Morley remained united with that of Montague until the death of William's grandson Thomas about 1686, when it fell into abeyance.

John Parker, 1st earl of Morley (1772–1840), only son of John Parker (1735–1788), who was created Baron Boringdon in 1784, but was no relation of the previous barons Morley, was a prominent supporter of Pitt and of Canning. In 1815 he was created earl of Morley. He was a public benefactor to Plymouth and its neighbourhood. He was succeeded by his son Edmund Henry Parker (1810–1864), whose son, Albert Edmund, the 3rd earl (1843–1905), was chairman of committees in the House of Lords from 1889 to 1905, after having been under-secretary for war and first commissioner of the navy. In 1903 his son, Edmund Robert, 4th earl (d. 1917), was succeeded by his nephew, John Riddell Parker, 5th earl (d. 1948).

MORLEY, GEORGE (1597–1684), English bishop, was born in London and educated at Westminster and Oxford. In 1640 he was presented to the sinecure living of Hartfield, Sussex, and in the following year he was made canon of Christ Church and exchanged to the rectory of Mildenhall, Wiltshire. He preached before the Commons in 1642, but his sermon gave offence, and when in 1647 he took a prominent part in resisting the parliamentary visitation of Oxford University he was deprived of his canonry and living. Leaving England he joined the court of Charles II., and became one of the leading clergy at The Hague. Shortly before the Restoration he came to England on a highly successful mission to gain for Charles the support of the Presbyterians. In 1660 he regained his canonry, and soon became dean of Christ Church. In the same year he was consecrated bishop of Worcester. At the Savoy conference of 1661 he was chief representative of the bishops. He was translated to the see of Winchester in 1662. His works are few and not very regular, e.g. The Bishop of Worcester's Letter to a Friend for Vindication of himself from the Calumnies of Mr. Richard Baxter (London, 1662).

MORLEY, HENRY (1822–1894), British man of letters, was born in London on the 15th of September 1822. After unhappy experiences at English schools, he was sent to the Moravian school at Neuwied, whose system strongly influenced his subsequent theories of education. It was intended that he should follow his father's profession of medicine, and in 1844 he bought a share in a practice at Madeley, Shropshire. Plunged into debt by his partner's dishonesty, he set up a small school for young children at Liscard, near Liverpool. His principle was to abolish all punishment, to make his pupils regard their work as interesting instead of repellent, and to form their character by appealing exclusively to higher motives. This scheme, carried out with much ingenuity, proved a complete success. Meanwhile he had devoted his spare time to writing. His contributions to magazines attracted the notice of Charles Dickens, on whose invitation in 1851 he settled in London as a regular contributor to Household Words. He was also on the staff of the Examiner, which he edited from 1861 to 1867. Meanwhile he had devoted much research to a life of Palissy the Potter (1852), which was at the same time a picture of life in medieval France. Encouraged by its favourable reception, he followed it up with lives of Jerome Cardan (1854) and Cornelius Agrippa (1856), and subsequently of Clement Marot (1870). His dramatic criticisms were reprinted in 1866 under the title of The Journal of a London Playgoer, 1851–1866. In 1857 he was appointed evening lecturer in English literature at King's College, and in 1865 became, in succession to David Masson, professor of English literature at University College, London. His First Sketch of English Litera-

ture (1873), a comprehensive and useful manual, reached its 34th thousand during the author's lifetime. He published in 1864 the first volume of a monumental history of English literature entitled English Writers, which he eventually carried in eleven volumes down to the death of Shakespeare. He was indefatigable as a popularizer of good literature. After editing a standard text of Addison's Spectator, he brought out a vast number of classics at low prices in Morley's Universal Library, Cassell's National Library, and the Carisbrooke Library. His ready speech, retentive memory, earnest purpose, and bright style made him perhaps the most popular lecturer of his day. His teaching work at University College was marked by equally extraordinary success. In 1882 he accepted a post that made great calls on his time and energy—the principalship of University Hall. This institution was partly a residence for students of University College, and partly the home of Manchester New College. During this time he rendered further services to the cause of education in London not only by his work on the council of University College, but by his advocacy of a teaching university for London. In 1886 he resigned the principalship of University Hall and his professorship at University College, and removed to the Isle of Wight, intending to devote his leisure to the completion of the great task of his life, English Writers. But with his work only half achieved he died on the 14th of May 1894.

MORLEY [OF BLACKBURN], JOHN MORLEY, VISCOUNT (1838–1909), English statesman and author, was born at Blackburn on the 24th of December 1838, being the son of Jonathan Morley, surgeon. He matriculated at Lincoln College, Oxford, in 1856, and after taking his degree in 1859 came up to London with the determination of seeking distinction by literature. He almost immediately became editor of the moribund Literary Gazette, which not all his ability could preserve from extinction. Gradually, however, he became known as a philosopher and a Radical, and as one of the ablest and most incisive contributors to the literary and political press of the day. His sympathies as a thinker seem to have been at this time chiefly with Positivism, though he never embraced Comte's doctrine in its hierarchical aspects; but he acquired a reputation as an agnostic, which became confirmed in the popular mind when he somewhat abruptly spelt out his faith in a small "g." In 1868 he was editor for a short time of the daily Morning Star, which came to an end in 1870. In 1897 he succeeded G. H. Lewes in the editorship of the Fortnightly Review, which he conducted with brilliant success until 1893, when he was elected to parliament; he then assumed in exchange, but not for long, the lighter duties of the editorship of Macmillan's Magazine. He had been connected with Messrs Macmillan since the commencement under his editorship in 1878, of the "English Men of Letters" series, a collection of biographies of various merit, in which nothing is better than the editor's own contribution in his Life of Edmund Burke, itself an extension of his article in the 9th edition of this encyclopaedia (1876). Since 1886 he had also been editor of the Pall Mall Gazette, which had been turned into a Liberal paper (see NEWSPAPERS).

In 1883 Mr Morley, who had twice unsuccessfully attempted to enter parliament, was returned for Newcastle-upon-Tyne at a by-election. The prestige thus acquired led to his presiding over a great Liberal congress at Leeds in the same year; and, although this platform never seemed his natural element, the literary finish of his style and the transport of honesty of his reasoning rapidly gained him a prominent position in the House of Commons. When, in February 1886, Mr Gladstone returned to office as Home Ruler, Mr Morley, who had never before held any public appointment, filled one of the most important posts in the cabinet as secretary for Ireland. He had always expressed his sympathy with the Irish Nationalist movement. He had no opinions to recant, no pledges to explain away. He is credited with an especial influence over Mr Gladstone in the matter of Home Rule, and in particular with having kept him steady in the Bill of 1886 to its original purpose of entirely separating the Irish from the British legislature, a provision which pressure
from their own party afterwards compelled both of them to abandon. After the severe defeat of the Gladstonian party at the general election of 1886, Mr Morley led a life divided between politics and letters until Mr Gladstone's return to power in 1892, when he resumed his former office. He had been re-elected for Newcastle in circumstances entirely honourable to himself, a determined attempt having been made to exclude him in consequence of his resistance to an Eight Hours' Labour Bill, of which he disapproved as an undue interference in principle with the rights of adult labour. His constituents showed their appreciation of his integrity by returning him with a majority of 1739; but the resistance to his views on the labour question went on in his constituency, and was assisted by Joseph Cowen's persistent campaign in the principal Newcastle newspaper against the general lines of Mr Morley's somewhat doctrinaire and anti-Imperialistic views on politics. The result was that at the election of 1895 he lost his seat, but soon found another in Scotland, for the Montrose Burghs. He had during the interval taken a leading part in parliament, but his tenure of the chief secretaryship of Ireland was hardly a success. The Irish gentry, of course, made things as difficult for him as possible, and it was not till the dissolution of the Irish University in office at Dublin Castle that he felt himself in a basket with pitfalls. In the intestine disputes which agitation the Liberal party during Lord Rosebery's administration, and afterwards, Mr Morley sided with Sir William Harcourt, and was the recipient and practically co-signatory of his letter resigning the Liberal leadership in December 1898.

Mr Morley's activities were now again turned to literature, the political views most characteristic of him, on the Boer war in particular, being practically swamped by the overwhelming predominance of Unionism and Imperialism. His occasional speeches, however, denouncing the Government policy towards the Boers and towards the war, though not representing the popular side, always elicited a respectful hearing, if only for the eloquence of their language and the undoubted sincerity of the speaker. As a man of letters his work was practically concluded at this period, and may briefly be characterized. His position as a leading English writer had early been determined by his monographs on Voltaire (1874), Rousseau (1873), Diderot and the Encyclopaedists (1875), Burke (1879), and Walpole (1880). Burke as the champion of sound policy in America and (as Mr Morley deems) of justice in India, Walpole as the pacific minister understanding the true interests of his country, fixed his imagination.

His Life of Oliver Cromwell (1900) revises Gardiner as Gardiner revised Carlyle. The Life of Cobden (1881) is an able defence of that statesman's views rather than a critical biography or a real picture of the period. Mr Morley's contributions to political journalism and to literary, ethical and philosophical criticism were numerous and valuable. They show great individuality of character, and recall the personality of John Stuart Mill, with whose mode of thought he had many affinities. As in letters, so in politics. A philosophical Radical of a somewhat mid-19th-century type, and highly suspicious of the later opportunistic reaction (in all its forms) against Cobdenite principles, he yet retained the respect of the majority whom it was his usual fate to find against him in English politics by the incontestable consistency of his principles and the sheer force of character and argumentation and utterance.

After the death of Mr Gladstone Mr Morley was principally engaged upon his biography, until it was published in 1903. Representing as it does so competent a writer's sitting of a mass of material, the Life of Gladstone was a masterly account of the career of the great Liberal statesman; traces of Liberal bias were inevitable but are rarely manifest; and in spite of the a priori unlikelihood of a full appreciation of Mr Gladstone's powerful religious interests from such a quarter, the whole treatment is characterized by sympathy and judgment. Among the coronation honours of 1902, Mr Morley was nominated an original member of the new Order of Merit; and in July 1902 he was presented by Mr Carnegie with the late Lord Acton's valuable library, which, on the 20th of October, he in turn gave to the university of Cambridge.

When Sir Henry Campbell-Bannerman formed his cabinet at the end of 1905 he was made secretary of state for India. In this position he was conspicuous in May 1907 and afterwards for his firmness in sanctioning extreme measures for dealing with the outbreak in India of alarming symptoms of sedition. Though he was bitterly attacked by some of the more extreme members of the Radical party, on the ground of belying his democratic principles in dealing with India, his action was generally recognized as combining statesmanship with patience; and, though uncompromising in his attitude towards revolutionary propaganda, he showed his popular sympathies by appointing two distinguished native Indians to the council, and taking steps for a decentralization of the administrative government. When Sir Henry Campbell-Bannerman resigned in 1908 and Mr Asquith became prime minister, Mr Morley retained his post in the new cabinet; but it was thought advisable to relieve him of the burden imposed by a seat in the House of Commons, and he was transferred to the upper house, being created a peer with the title of Viscount Gladstone of Blackburn. His subsequent career at the India office will always be associated with his extensive and far-reaching reforms of the system of government in India so as to introduce more fully the representative element (see INDIA).

Whatever might be the outcome of this crucial reform, the preparation and execution of Lord Morley's scheme were carried through by him with a statesmanlike and philosophic detachment, and in a spirit of balanced reason, which earned for him the increased respect of all parties in the state. (H. Ch.)

MORLEY, SAMUEL (1809-1886), English manufacturer and politician, was born at Homerton, not then a part of London, on the 15th of October 1809, the youngest son of a Nottingham hosier. His father, John, and his uncle, Richard, were the founders of the already prosperous Nottingham firm of I. & R. Morley, dealers in hosiery made in the cottages of the local Knitters, and as early as 1797 they had opened a London warehouse, in the counting-room of which Samuel Morley began his career at sixteen. On his father's retirement in 1826 he became the practical head of the London concern, and when his brothers retired in 1855 sole owner. In 1860 he was sole owner also of the Nottingham business. Under his excellent management the business grew rapidly into the largest of the kind in the world, with huge mills at Nottingham and in Leicestershire and Derbyshire employing thousands of hands. In 1865 Morley was elected M.P. for Nottingham, and from 1866-1885 he sat for one of the Bristol divisions. He was a strong Liberal and a whole-hearted supporter of Gladstone, who in 1885 offered him a peerage. He was one of the principal proprietors of the London Daily News, the chief Liberal organ of the period, and it was owing to him that its price was reduced from 3d. to 1d. and its losses turned to great gains. Morley was a deeply religious man. Like his father before him, he was a Dissenter, and for many years he strongly opposed every scheme of state interference with education. He was keenly interested in the temperance movement, and during the closing years of his life his public energies were chiefly confined to its promotion. His philanthropy was active, his charity widespread and munificent, and he was a model employer. He died on the 5th of September 1886. His son, Arnold Morley (b. 1849), was Liberal M.P. for Nottingham from 1880-1885, and for East Nottingham from 1885-1895. From 1886-1892 he was chief Liberal whip, and from 1892-1895 postmaster-general.

See Edwin Hodder, Life of Samuel Morley (1887); Frederic M. Thomas, I. & R. Morley: a Record of a Hundred Years (1900).

MORLEY, THOMAS (1557-1603). English musical composer, was born in 1557, as may be gathered from the date of his motet, "Domine non est," composed "aetatis suae 19 anno domini 1576," and preserved in Sadler's Part-Books (Bodleian Library). He was a pupil of William Byrd, but nothing is known as to his origin and very little as to the incidents of his career. In the account of the entertainments given at Elvetham by the earl of Hertford in 1591 in honour of Queen Elizabeth, it is stated that there was "a notable consort of six Musitions," whose music so pleased the queen "that in grace and favour thereof, she gave
MORLEY—MORMONS

a newe name unto one of their Pavanos, made long since by Master Thomas Morley, then Organist of Paules Church." This statement, however, later corroboration said if Morley ever held the post he must have done so for a very short time. On the 5th of July 1588 he was admitted Mus. Bac. at Oxford. Four years later (July 24, 1592) he entered the Chapel Royal, where he successively filled the offices of epistol and gospeller. From the dedication to his first book of canzonets it seems that in 1595 Morley was married. His wife's Christian name was Margaret, and before her marriage she apparently held some post in the household of Lady Periam, wife of the lord chief baron of the exchequer. On the 11th of September 1598 Morley received a licence for twenty-one years to print ruled music-paper and song-books in English, Latin, French or Italian. His rights under this grant were assigned by him to various publishers. In Burgeon's *Life of Gresham* it is stated (ii. 405) that the registers of St Helen's, Bishopsgate, show that Morley lived in that parish. This is inaccurate, and there is no proof that the family of the same name residing in St Helen's between 1594 and 1600 was related to the composer. In the preface to his *Plaine and Easie Introduction to Practicall Musique* (1597), Morley gives as one of his reasons for undertaking that work that he led a sordid, short period of his life was spent in illness. On the 7th of October 1602 his place in the Chapel Royal was filled up, and on the 25th of October 1603 administration of his goods was granted to his widow. This document (Act Book, 1603, fol. 171) describes him as "late parishioner of St Botolph's near Billingsgate," but the registers of that parish contain no entries relating to him. Morley was incontestably one of the greatest of the secular Elizabethan composers. His madrigals, canzonets and ballets are as remarkable for their beauty as they are for their admirable workmanship, and his *Introduction to Practicall Musique*, in spite of its frequent obscurity, is an invaluable source of information as to the state of musical science in England at the end of the 16th century. His works are: (1) Canzonets to Three Voices (1593; 2nd ed., 1606; 3rd ed., 1631; Ger. trans.: Cassel, 1612, and Rostock, 1624); (2) Madrigals to Four Voices (1594; 2nd ed., 1600; (3) First Book of Ballets to Five Voices (1595; an Ital. ed. appeared in London in the same year; 2nd ed., 1600; Ger. ed., Nuremberg, 1609); (4) First Book of Canzonets to Two Voices (1595; 2nd ed., 1601); (5) First Book of Canzonets to Three Voices (1595; 2nd ed., 1600); (6) First Book of Canzonets to Four Voices (1595; 2nd ed., 1600); (7) First Book of Canzonets to Five Voices (1595; 2nd ed., 1600); (8) The First Book of Consort Lessons, made by divers authors, &c. (1599; 2nd ed., 1611); (9) The First Book of Airs to Sing and Play to the Lute with the Base Viol (1600); (10) The Triumphs of Oriana to Five and Six Voices, composed by divers several authors (1601). Besides the above, services, anthems, motets and virginal pieces by Morley are to be found in various collections, both printed and manuscript.

(W. B. S.)

MORLEY, a municipal borough in the Morley parliamentary division of the West Riding of Yorkshire, England, 4 m. S.S.W. of Leeds, on the Great Northern and London & North-Western railways. Pop. (1901), 23,636. The town-hall was erected in 1895; and a park, for which the ground was presented by Lord Dartmouth, in 1890. The chief industries are connected with woolen cloth, machinery for the treatment of wool, coal and stone. The borough, so termed in 1835, is noted a market, 8 aldermen and 21 councillors. Area, 1,535 acres. In the neighbouring are towns of a mansion, Howley Hall, dating from 1500, which, garrisoned for the parliament, sustained a heavy siege from the royalists during the Civil War.

MORMAO, or MORMAER (from two Gaelic words mor, great, and maor, a steward or bailiff), a title used to designate the rulers of the seven provinces into which Celtic Scotland, i.e. the part of the country north of the Forth and the Clyde, was divided. These seven Mormao-ships, or original "earldoms" of Scotland, as they were afterwards called, were: Angus, Athole with Gowry, Caithness with Sutherland, Fife, Moray with Buchan, Moray with Ross, and Stratherne with Menteith.

MORMONS, the common name given to the Church of Jesus Christ of Latter-Day Saints, a religious sect founded by Joseph Smith, jun., at Manchester, New York, in 1830, and since 1838 largely concentrated about Salt Lake City, Utah. Smith was born on the 23rd of December 1805 at Sharon, Windsor county, Vermont, from which place in 1815 or 1816 his parents, who like his grandparents were superstitious, neurotic, seers of visions, and believers in miraculous cures and in heavenly voices and direct revelation, removed to New York, where they settled on a small farm near Palmyra, Wayne county (then Ontario). In 1819 they removed to Manchester, in what is still Ontario county, about 6 m. from Palmyra. In Manchester Joseph, a good-natured, lazy boy, suffering from a bad heredity physically and psychically, began to have visions which seem to have accompanied epileptic seizures (his mother's father had falling fits), from which he recovered apparently before he became of age. The boy's father was a digger for hidden treasure and used a divining rod to find proper places to dig wells, and about this time the son became a crystal gazer and by the use of a "peep-stone" discovered the whereabouts of pretended hidden treasure.

The Mormon movement developed from a religious sect, and told him that the Bible of the western continent, the supplement to the New Testament, was buried on a hill called Cumorah, now commonly known as Mormon Hill. It seems almost certain that he told other and earlier stories of how he came to find the gold plates, and it is possible that before this time there was a story current in Canada of the discovery of a "Gold Bible." It was not until the 22nd of September 1827 that (as he said) he dug up, on the hill near Manchester, a stone box, in which was a volume, 6 in. thick, made of thin gold plates 8 in. by 7 in. and fastened together by three gold rings. The plates were covered with small writing in characters which, it was said, Professor Charles Anthon declared were in the "reformed Egyptian tongue"; with the golden book Smith claimed that he found a breastplate of gold and a pair of supernatural spectacles, consisting of two crystals set in a silver bow, and called "Urim and Thummim"; by aid of these the mystic characters could be read. Being himself unable to read or write fluently, Smith employed as amanuenses: a man named John Kyriss and a Nephite woman named Emma; after the middle of April 1829, Oliver Cowdery, a blacksmith and school teacher; and David Whitmer (1805-1888); to them, from behind a curtain, he dictated a translation, for the printing and publishing of which Martin Harris paid, in spite of the continued opposition of his wife to the scheme. An edition of 5000 copies of *The Book of Mormon* was printed early in 1830 in the printing office of the *Wayne Sentinel* at Palmyra. It was accompanied by "The Testimony of the Three Witnesses," a sworn statement of Oliver Cowdery, David Whitmer and Martin Harris that an angel of God had shown them the plates of which the book was a translation, and by "The Testimony of the Eight Witnesses," four of them Whismers and three of them Smiths (Joseph's father and he brother Hyrum and Samuel). Soon afterwards, according to Smith, the plates disappeared, being taken away by the angel Moroni.

The Book of Mormon, in which Joseph Smith was declared to be God's "prophet," with all power and entitled to all obedience,

1 Martin Harris took a copy in Smith's hand of certain "carac- tors" (so Smith spelled it) to Dr Anthon, who at first thought it "a hoax upon the learned," but, after hearing the story of the diamond spectacle, and that Harris had been asked to pay for the book which was given to him by the foreigner, he was convinced. He had recognized the miscellaneous and haphazard nature of the "carac- tors," of which facsimiles are given by Riley, p. 81, and Linn, p. 40. Riley thinks that the "caracters" were automatic writing, and that unconsciously composition played a large part in the evolving of the gold plate scheme.

2 More than a dozen years afterwards Smith, when asked if "Mormon" was not connected with the Greek word for "hobgoblin" ("Moro" is thus used in 17th-century English), explained that it meant "more good," from the "Egyptian mon," with the addition of more, or the contraction mor."
MORMONS

843

professes to give the history of America from its first settlement by a colony of "Jaredites" from among the crowd dispersed by the confusion of tongues at the Tower of Babel down to the year 30 a.d. These settlers in course of time destroyed one another. In 600 B.C., Lehi, his wife, and four sons, with ten friends, all from Jerusalem, landed on the coast of Chile. Upon the death of Lehi, the divine appointment to the leadership of Nephi, the youngest son, roused the resentment of his elder brothers, who were in consequence condemned to have dark skins and to be an idle, mischievous race, the "Lamanites" or North-American Indians. Between the Nephiites and the bad Hebrews a fierce war was maintained for centuries, until, finally, in spite of divine intervention in the person of the risen Christ, who here founded a Church with the same organization as was enjoyed on the Eastern Continent," the Nephiites fell away from the true faith, and in 384 A.D. were nearly annihilated in a battle at the hill of Cumorah, in Ontario county, New York. Among the handful that escaped were Mormon and his son Moroni, the former of whom collected the sixteen books of records, kept by successive kings and priests, into one volume, which on his death was supplemented by his son with some personal reminiscences and by him buried in the hill of Cumorah, where they are said by New Jerusalemites to be buried, if they could be discovered by God's chosen prophet.

This Smith's account of the book: it was a contention of the early anti-Mormons, now however discredited, that The Book of Mormon as published by Smith was rewritten with few changes from an unpublished romance, The Manuscript Found, written before 1812 by Solomon Spaulding (1761–1816), a minister and iron-founder who had become greatly interested in the prehistoric mounds of Ohio and wrote a romance to explain their origin and the Hebrew origin of the North-American Indians. The style of the book is poor; the speeches of primitive Indian chiefs are filled with the phraseology of the 19th-century camp-meeting; there are long extracts from the Westminster Confession, and a speech of Nephi contains a statement of doctrine which corresponds with heretical views held in Smith's own time in the presbytery of Geneva, in which his home lay.

The time was singularly favourable to the founding of a new sect: religious unrest and receptiveness were prevalent; and western New York was the scene of the foundation of various new communities. Between the years 1820 and 1825, when Jemima Wilkinson founded "Jerusalem" in Yates county, New York, and in 1828, when the Fox sisters gave their first spiritualistic manifestations about ten miles from Joseph Smith's home. His book and his claim to divine authority, upheld by frequent revelations, soon drew many followers to Smith. A Church was formally organized on the 6th of April 1830 at Fayette, Seneca county, New York; and in June a conference of about thirty members met at Fayette. Smith and Cowdery had previously (May, 1829) baptized each other, in alleged accordance with the instruction of John the Baptist, who had ordained them, conferring "the priesthood of Aaron"; while Peter, James and John afterwards made them priests of "the order of Melchisedec.

It was supposed that Sidney Rigdon had been a compositor in a Pittsburg shop and that he had started on his own, having left this office, or had made a surreptitious copy of it, and that he entered into a plot with Smith to use this material for a new Bible.

In support of these are vague stories of a mysterious visitor to Smith at the time he was making his translation; and the argument that Smith did not, and Rigdon did, know enough to get the book in shape. But there is no actual proof that Rigdon lived in Pittsburg or was employed in a printer's shop there as early as when Spaulding's copy had been left with the printer; and it is plain from the circumstances that Rigdon had nothing to do with anything of Mormonism until after the publication of The Book of Mormon.

The discovery by Professor J. H. Fairchild, in 1884, in Honolulu of a manuscript romance by Spaulding (now in the library of Oberlin College, Ohio), which did not agree at all with Smith's, is nothing to the point. The Book of Mormon, does not in any way settle the matter, as this romance is so different in character from the story read by Spaulding to some of his friends in 1811–1812, that if it was really Spaulding's, it must have been a later work than The Manuscript Found. Even, however, if it be true that Smith used Spaulding's story, his own additions to it must have been large, for parts of the Book seem autobiographic, and one incident seems to be based on the anti-Masonic excitement prevalent in New York at the disappearance of William Morgan in 1826—ten years after the death of Solomon Spaulding.

In October 1830 Smith sent out Parley Parker Pratt (1807–1857), Oliver Cowdery, Ziba Peterson, and Peter Whitmer, jun., as missionaries. One of their first converts, in Mentor, Lake county, Ohio, was Sidney Rigdon (1793–1876), whom Pratt had formerly known, who had preached as a Baptist in 1819–1828—a part of this time in Pittsburg—where he had then joined Alexander Campbell and Walter Scott in establishing the Disciples of Christ, and who was pastor of a church in Mentor. Rigdon was baptized, became a Mormon leader, and, after a "revelation" of December 1830, made a new translation of the Bible, in which prophecies of the coming of Joseph Smith and the nature of The Book of Mormon are inserted in the 50th chapter of Genesis and the 29th chapter of Isaiah respectively. This translation was not published until 1866 and is not in use in the Mormon churches. In January 1831 Smith, who had been "persecuted" in his New York home, where several lawsuits, all unsuccessful, had been brought against him, accompanied Rigdon to Ohio, where at Kirtland (a few miles south-west of Mentor), Lake county, Ohio, the preaching of the new sect was very successful, partly because Pratt and Rigdon were so well known to the Disciples in north-eastern Ohio. Smith at this time seems to have intended to make the new colony at Kirtland, there he established a general store, a steam-saw-mill and a tannery. He took land, platted a great city, and built a stone temple, which was consecrated in 1836. But the church was "persecuted" again, especially by apostates; on the 25th of March 1832 Smith and Rigdon were tarred and feathered at Hiram, 2 Portage county, where they were then living. In February 1834 the Church was fairly organized; already on the 5th of March 1833 Smith, Rigdon, and Frederick G. Williams had been styled the first presidency, and were entrusted with the keys of the last kingdom.

About this time the licentiousness of Smith might have led to the dissolution of the Church but for Brigham Young (1801–1877), a Vermont painter and glazier, who was baptized in 1832 and soon afterwards was ordained elder. Young's indomitable will, perseveraive eloquence, executive ability, shrewdness and zeal soon made their influence felt, and, when a further step was taken in 1835 towards the organization of a hierarchy by the institution of the quorum of the "twelve apostles," 19 who were sent out as proselytizing missionaries among the "gentiles," Young was made a member of the Twelve and deputed to travel through-out the eastern states. In 1836 the Kirtland Safety Society Bank was organized (in accordance with a "revelation" to Smith); as it was unchartered it issued notes under the name of "The Kirtland Safety Society anti-Bank-ing Co." 20; but in March 1837 Rigdon and Smith, the secretary and treasurer, were charged with violating the state law against unchartered banks, and they were convicted in October; the society appealed, claiming that it was not a bank but an association, but in November the "bank" suspended payments and in Jan. 1838 Smith and Rigdon left the state for Missouri. In 1836–1837 there had been a determined attempt to depose Smith and make David Whitmer head of the Church; Rigdon and Young successfully opposed this movement, which was backed by Whitmer, Pratt, Williams and Harris. Probably in June 1837 (or in July 1838) there was organized under the leadership of Captain "Fear Not" (David W. Patten) a band called "The Daughter of Zion" (see Mic. iv. 3), the "Big Fan" (Jer. xv. 7), "Brothers of Gideon," and finally "Sons of Dan" (Gen. xlii. 17), bound to secrecy under penalty of death, and whose object was to punish all who opposed the Church and its supreme head. Numerous crimes and outrages were attributed to them. 21

2 Rigdon had formerly been well known and respected in Hiram, which was a stronghold of the Disciples; there he had taught Latin and Greek. The Book of Mormon, does not tell how he got the Book of Mormon. It is possible that Rigdon adopted this name for himself at this time, and that he had no knowledge of the book until after the publication of The Book of Mormon.

3 Young received at this time the title of "The Lion of the Lord"; Lyman Wright and Parley Pratt, who also became apostles, were called respectively, "The Wild Ram of the Mountains" and "The Archer of Paradise."

4 The existence of this organization has been denied by Mormons, but there is abundant evidence that it did exist. See Linn, pp. 212–214, and Bancroft, pp. 124–126; the latter, friendly to the Mormons, says (p. 124) that of the existence of the Danites "there is no question."
of 1830–1831 Pratt, Cowdery and two others had gone as far west as Jackson county, Missouri; in June 1831 Rigdon and Smith joined them there near what is now Independence and (in August) laid corner-stones of Zion and of a Mormon temple; thereafter Mormon immigration to Missouri increased rapidly; and in the early part of 1838 Smith and Rigdon fled to the new settlement called Far West (now Kerr) in Caldwell county, Missouri, which had been made in 1836–1837. Thither many of the saints had taken refuge, having been forcibly driven 1 from Independence and Big Blue in November and December 1833, and having been induced to remove from Clay county after staying there in 1833–1836. In Caldwell and Daviess counties Smith's troubles, however, continued to increase. His proclivities had repelled many of his leading supporters and bred internal dissensions, while from the outside the brethren were harassed and threatened by the steadily growing hostility of the native Missourians.

At Far West on the 4th of July 1838 Rigdon preached his "salt sermon" from Matt. v. 13, urging his hearers to wage "a war of extermination" on those who disturbed them. To such a height did the conflicts with the "gentiles" grow that they assumed the proportions of a civil war, and necessitated the calling out of the state militia. A company of Danites from Far West put some Missourian militia to flight but lost their own leader Captain Patten; the gentiles then attacked a Mormon settlement at Hawn's Mill (near Far West) and killed in cold blood about a score of the Mormons. Later in October Far West was invaded by another overwhelming force of militia. Smith and Rigdon and others were arrested and imprisoned on a charge of treason, murder and felony, and their followers to the number of 15,000 crossed over into Illinois and settled near Commerce, Hancock county. Smith, who succeeded in escaping from custody, had rejoined the Mormons in Illinois, and there they were cordially welcomed, especially by the politicians of both parties, who hoped to secure the Mormon vote in the presidential campaign of 1840; and when they founded (on the site of Commerce) the city of Nauvoo, they readily obtained (Dec. 1840) from the state legislature a charter which made the city practically independent of the state government and gave Smith nearly unlimited civil power. He organized a military body called the Nauvoo Legion (also incorporated by the legislature), of which he was commander, being commissioned "lieutenant-general" by the governor of Illinois in 1841; Smith allowed Dr. John C. Bennett, an Illinois politician and a new convert, to be the city's first mayor. Foundations of a new temple were laid on the 6th of April 1841 and the temple (83 by 128 ft.) was dedicated on the 1st of May 1846. The city grew very rapidly; a university of the city of Nauvoo was established, among its professors being Rigdon and Orson Pratt (1811–1885), a mathematician, who was called "The Gauge of the Law." In 1842 Smith was charged with instigating an attempt, made by O.P. Rockwell, a Mormon of Nauvoo, to assassinate ex-Governor L. W. Boggs of Missouri; it was impossible to hold either Rockwell or Smith after their indictment and arrest, since the Nauvoo municipal court had the power to determine cases of habeas corpus; the influence of Dr. Bennett, who had quarreled with Smith, was not strong enough to outweigh the power of the Mormon vote with the state authorities, and Smith was not haled when in June 1843 he was arrested on the old charge of treasonable acts committed in Missouri. His downfall was brought about in a very different manner.

The Book of Mormon had forbidden polygamy: "There shall not any man have save it be one wife, and concubines he shall have none, for I the Lord God delighteth 2 in the chastity of women. . . . For if I will, saith the Lord of Hosts, raise up seed unto me, I will command my people, otherwise they shall hearken unto these things." The conditional clause may indicate that Smith from the first had intended to make polygamy a part of the creed of the Church. There is some evidence that even in Ohio polygamy had been secretly practised by Smith and less probably by other elders. In Illinois there seems to have been no secret about Smith's cohabiting with other women. On the 12th of July 1843 he had a revelation expressly establishing and approving polygamy. This revelation was not published officially until 1852, but its purport immediately became known in Nauvoo and aroused great indignation. Dr. R. Foster, whose wife Smith seems to have coveted, and whom Smith had accused of theft and immorality, William Law and Wilson Law, wealthy Canadian converts, and Sylvester Emmons, a member of the council, established a newspaper the Expositor, which was to work for the repeal of the city charter, "to correct the abuse of the unit power, to advocate disobedience to political revelations"; the first and only number (June 7, 1844) told of Hyrum Smith's reading to the council the "revelation on the eternity of the marriage covenant, including plurality of wives," of Joseph Smith's methods and success in winning spiritual wives, and of the prophet's political ambitions. The city council tried the editors of the Expositor, the Smiths denying the "revelation" on plural marriage; and on the 10th of June the Expositor printing office was razed. Foster and the Laws fled to Carthage. There was a general uprising against the Mormons and Smith put Nauvoo under martial law; but his most able lieutenants were absent, 3 the legion surrendered its arms, and Joseph and Hyrum Smith and others were arrested on the charge of treason (June 27, 1844) and were sentenced at Carthage. On the night of the 27th a mob, with the collusion of the militia guard, broke into the prison and shot the two brothers dead.

Rigdon, the survivor of the first presidency, and Brigham Young, who were absent from Illinois at the time of Smith's death, were rivals for Smith's place; Young succeeded in having the Council of Twelve, of which he was head, make the supreme authority, and then had Rigdon 4 tried for threatening treason and "cut off from the Church." Young had still to meet the opposition of Joseph Smith's family, who claimed for his son, Joseph, the right of succession, and for a time supported the claims of James J. Strang (1813–1856) of Wisconsin, who had been baptized in February 1844, who told of revelations he had received, who settled with his followers on Beaver Island, Michigan, in 1847, was crowned "King of Zion" there in July 1850, and was killed by some of his followers there in June 1856, when his kingdom broke up. In January 1845 the Nauvoo city charter was repealed; hostility and suspicion against the Mormons increased; there were "burnings" of Mormon property in the outlying country and retaliation by the Nauvoo Legion under a pro-Mormon sheriff; a commission of four members (including Stephen A. Douglas), appointed by the governor, arranged with the Mormons that they should all leave the state next spring. In May and June 1846 most of the Mormons left Nauvoo; in September the city was cannonaded and it again surrendered to the gentiles.

Five companies of Mormon volunteers joined the force under Colonel Stephen W. Kearny which marched to California in the winter of 1846–1847; but this was rather in the nature of assistance from the general government, which provided for their western transportation, than a proof of Mormon patriotism. An exploring party under Brigham Young entered (July 24, 1847) the Great Salt Lake valley and chose it as a place for their new city. Young then returned to Winter Quarters, near what is now Florence, Nebraska, and there on the 5th of December 1847 was chosen president as Smith's successor. Under his leadership, and in accordance with a scheme "revealed" to him and announced in January 1847, the march was organized in a

1 Brigham Young, Orson Pratt, and others of the Twelve were campaigning for Smith's candidacy for president of the United States, a campaign which he had undertaken because neither Henry Clay nor John C. Calhoun would give him satisfactory pledges as to the position of the Mormons if elected president.  
2 Rigdon attempted, with brief success, to establish in Pittsburg a Church of Christ, independent of the Latter Day Saints, but based on much the same plan. He spent his last years at Friendship, Alleghany county, New York.
MORMONS

The Church; tired and discouraged, they abandoned the enterprise, and the names of those who had been killed remained on the prairies to mark the spot where the Mormons had been "sown among the Gentiles".

The judgment of the United States against the Mormons was made in 1857, on the ground that they had violated the laws of the Territory and the Constitution of the United States. The Mormons were ordered to pay a fine of $500,000, or to be imprisoned for life, unless they surrendered their property to the United States.

The Mormons appealed to the Supreme Court of the United States, and the case was heard by the Court on November 11, 1857. The Court decided in favor of the Mormons, and ordered them to pay a fine of $500,000, or to be imprisoned for life, unless they surrendered their property to the United States.

City it became increasingly difficult for the Mormon authorities to prevent trade with gentile stores in the city; and in 1869 there was incorporated the Zion Co-operative Mercantile Institution, to which practically all retailers in the territory were forced to sell out. In 1869 the Pacific Railroad reached Salt Lake City and by lessening its isolation, lessened its control by Young. His power was shaken somewhat, and the general tone of Mormonism was improved greatly by the "Godbeite movement," led by W. S. Godbe and E. L. T. Harrison, who with T. B. H. Stenhouse, author of The Rocky Mountain Saints (1874), Edward W. Tullidge, who wrote an official History of Salt Lake City, and others, had established in 1868 the Utah Magazine, which attacked Young's despotism. Although Godbe and Harrison were "cut off" from the Church they succeeded in founding the Salt Lake Tribune (1870), the first prominent protest in Utah against Young. At the same time the power of the Latter-Day Saints and Young's autocracy were threatened by the growth of the Reorganized Church of Jesus Christ of Latter-Day Saints, which was formed in 1852 upon the announcement of the doctrine of polygamy, which declared that polygamy had been foisted upon the Church and that Brigham Young was an interloper, and which chose Joseph Smith III. (son of Joseph Smith, jun.; born in 1832) as its head in 1860; in 1863 and in 1869 representatives of the Reorganized Church preached in Salt Lake City.

As early as 1862 Congress had passed the Morrill Act (introduced by Justin S. Morrill) "to punish and prevent the practice of polygamous marriages," but in 1867 the presiding officers of the Utah legislature, petitioning for the repeal of this act, declared that "the judiciary of this Territory has not, up to the present time, tried any case under said law." Attempts to pass some extreme measures in 1866 and in 1869-1870 failed. In October 1871 a grand jury in Utah indicted Young and others for violating a Territorial statute against improper cohabitation; but in April 1872 the Supreme Court of the United States (Chilton v. Englebrech) practically declared the jury incompetent as it had been impanelled by a Federal (and not by a Territorial) marshal, and in October 1873 the same court (Snow v. The United States) ruled that the attorney-general appointed by the president in a territory could try no cases save those in which the Federal government was a party, thus putting the prosecution of polygamy cases into the hands of the locally elected attorney-general. But on the 23rd of June 1874 President Grant signed the Colorado act, 1 in relation to courts and judicial officers in the Territories, of Utah, 2 which provided for prosecution by the United States attorney-general (not the local elected official) in criminal cases. In Federal courts in the Territory, for the impanelling of grand and petit jurors by the United States marshal, and for the challenge of any juror practising or believing in polygamy on a trial for adultery or polygamy, and otherwise corrected the defects in the Territorial law as pointed out by the Supreme Court, so that prosecutions for polygamy might no longer be a mere farce. But the law was little more than a dead letter: there were few prosecutions, and the only conviction was that of Young's secretary, George Reynolds, whose case dropped on from 1874 to 1879. In 1873 Ann Eliza Young, called "Wife No. 10," brought a suit for divorce against Brigham Young; the defendant was at various times imprisoned and fined for failure to pay alimony pendente lite; and in 1877 the judge decided that the marriage was void as polygamous.

Young died in Salt Lake City on the 29th of August 1877; he left an estate of more than $2,000,000, and was survived by about 25 wives and more than 40 children. The Church owes much to him, for he was an able leader. It has been said of him that he was "for daring a Cromwell, for intrigue a Machiavelli, for executive force a Moses, and for utter absence of conscience a Bonaparte." It must be borne in mind that to him, more than anyone else, there was the long struggle with the Church against the United States. His only doctrinal contribution to the Church was in 1832 when, in a sermon, he said that our Father could be none other than the first Man; that Adam came into the garden of Eden in a celestial body and with one of his wives; and that "He is our Father and our God, and the only God with whom we have to do."

Young's successor in the presidency—acting president from 1880—was John Taylor (1808-1887), an Englishman by birth, who was living at Toronto when P. P. Pratt converted him in 1836; he was a missionary in England in 1840; then went to Nauvoo and was wounded when Smith was killed; preached in France and Germany, and translated The Book of Mormon into French. His first councillor, appointed in 1880, was George Q. Cannon, who was probably the real administrator. On the 22nd of March 1882 President Arthur approved the Edmunds Act, drafted by George F. Edmunds of Vermont, which disfranchised polygamists in the Territories, made ineligible for jury duty in prosecutions for bigamy, polygamy, or unlawful cohabitation all who practised polygamy or believed in it, and made polygamy punishable by a maximum fine of $500 and imprisonment of not more than five years, and cohabitation of the Church more than one woman punishable by a maximum fine of $500, imprisonment for not more than six months, or both. The act was opposed because it was ex post facto. Under the Edmunds Act and the Edmunds-Tucker Act of March 1887 about 1200 persons were convicted of polygamy or unlawful cohabitation in Utah, Idaho and Arizona. The law was so rigidly enforced that about 12,000 were disfranchised, and the president of the Church had to spend his last years in hiding, and many other prominent Mormons escaped "on the underground."

The Edmunds-Tucker Act of 1887 dissolved the Perpetual Emigration Company and the corporation of the Church of Jesus Christ of Latter-Day Saints; and the Supreme Court in May 1890, on the ground that the Church was an organized rebellion, upheld the constitutionality of the confiscation of the Church property. On the 24th of September 1890 Wilford Woodruff (1837-1898), who had been chosen to succeed President Taylor in 1889, and who was himself a polygamist, issued a manifesto declaring "that my advice to Latter-Day Saints is to refrain from contracting any marriage forbidden by the law of the land;" and on the 6th of October the general council of the Church was dissolved by the Council of the Twelve and accepted "his declaration concerning plural marriages as authoritative and binding." This apparent recantment of "revelation" was explained by Mormon scholars as Smith had explained the abandonment of the New Jerusalem in Missouri—the Saints were prevented from carrying out the commands contained in a revelation, but as they had tried to obey, they would not be punished for disobedience. 3 On the 4th of January 1893, in response to a petition from the officials of the Church pleading the membership thereof to faithful obedience to the laws against polygamy, &c., President Harrison issued a general pardon to all liable to the penalties of the Edmunds-Tucker Act, on condition that they had not violated its provisions since the 1st of November 1890 and should not violate them in future. On the 4th of January 1896 Utah was admitted to the Union as a state, one of the conditions made by Congress being that polygamy should be prohibited by the state constitution, and that this prohibition be repealable only with the consent of the United States and of the people of the state; and article ii of the constitution reads: "The following ordinance shall be irrevocably without the consent of the United States and the people of this state: Perfect.

2 Woodruff was born in Connecticut, became a Mormon in 1832, in 1839 was made an apostle, in 1840 and in 1845 was a missionary to England, preached throughout the United States; wrote Leaves from my Journal (1881), and was called in the Church "Wilford the Faithful."

3 In 1831 the Order of Enoch, or United Order, was established, providing for a community of goods; when the people proved unable to keep this law, the "lesser law of tithing was given to them in 1838."
toleration of religious sentiment is guaranteed. No inhabitant of this state shall ever be molested in person or property on account of his or her mode of religious worship; but polygamous or plural marriages are for ever prohibited.

In March 1836 the escheated property of the Church still in possession of the United States government was restored, but the Church was not again incorporated, its legal business being transacted by its president as trustee-in-trust for the body of religious worshippers known as the Church of Jesus Christ of Latter-Day Saints; each ward of the Church has, however, been incorporated, and its bishop is its executive head. In 1838 President Woodruff died and was succeeded by Lorenzo Snow (1814–1901), a native of Ohio, converted to Mormonism in 1836. In 1838 Brigham Henry Roberts (b. 1857), an Englishman by birth and a Mormon leader, was elected to Congress from Utah; as he had three wives there was objection to his taking his seat in 1839 in the 5th Congress; and on the 25th of January 1900 by a vote of 21 to 10 he was excluded from his seat. In 1846 Reed Smoot (b. 1818), an apostle of the Church, was elected to the United States Senate, where there was an attempt to exclude him (not on the ground that he was a polygamist, for there was no suspicion of his having violated the law, but because the apostles of the Church still advocated polygamy); the Senate Committee on Privileges and Elections reported in favour of his exclusion; but on the 20th of February 1907 the Senate voted against his exclusion (42–28).

According to Smoot there were in 1906 not more than 500 householders in Utah who were polygamous; only six of the twelve apostles, and only one chosen since April 1900, were polygamous; and of the fourteen general authorities chosen between 1890 and 1906 twelve were monogamists.

Joseph Fielding Smith (b. 1838), a nephew of the prophet, being a son of Hyrum Smith, succeeded to the presidency in 1901; he was a polygamist, and in March 1907, soon after the birth of what was said to be his forty-third child, he pleaded guilty when charged with breaking the law against polygamy and was fined $50.

The growth of the Latter-Day Saints has been largely in foreign countries. Missionary work in southern Canada was begun in 1833 by Orson Pratt, and in 1836 his brother, Parley P. Pratt, organized a mission in Toronto; in 1837 the work was begun in Liverpool, which is still the headquarters in Great Britain; in Ireland the work met with little success; from Germany missionaries were expelled in 1851 and in 1853; the Book of Mormon was translated into Italian by Lorenzo Snow in 1853; a Hawaiian version was made in 1856 by George Q. Cannon; and the missions in Scandinavia were begun about 1850. In the earlier years of the Church all converts were urged to migrate to Utah, and the glowing accounts of life there doubled their number; the later policy of the Church, to which it was forced after 1850, Emigration Fund was dissolved and assisted immigration was for years by the Federal government, was for converts to remain in their native countries. In England (and to a lesser degree on the Continent) the announcement of the doctrine of plural marriage was a disadvantage to the Church, and many converts transferred their allegiance to the Josephites, or Reorganized Church of Jesus Christ of Latter-Day Saints, who always opposed polygamy and attempted to prove that such doctrines had been foisted on the Church by Brigham Young, who had supplanted Joseph Smith’s true successor, Joseph Smith III.

In 1908 the total number of Latter-Day Saints in the United States (chiefly in Utah and the neighboring states) was estimated at 700,000, while the total was about 600,000 members of the Reorganized Church. In Utah there are four great Mormon temples—at Salt Lake City (1893), Mantle (1888), Logan (1884) and St George (1877). The Reorganized Church has two temples; their legal successor is the Church founded by Joseph Smith, jun.; it holds that “the doctrines of polygamy, human sacrifice, or killing men to save them, Adam being God, Utah being Zion or the gathering place of the saints, are doctrines of devils”; its headquarters are in LaMotte, Iowa, whither it was removed from Plano, Illinois, in 1881; it has several churches in Canada, the largest being at London, Ontario, and Toronto, and it is the owner of a Temple lot at Kirtland, Illinois.

The Temple lot at Independence, Missouri, is owned by the small band of Mormon schismatics (organized in Illinois in 1835) who call themselves “The Church of Jesus Christ,” and are known as Hildrikkites; the Utah Church considers Independence as the holy city, and has made a temple there.

The general morality of the Mormons seems to have been high for a frontier community: there was no gambling nor drunkenness. The Saints, notably in the time of Brigham Young, were famed for their probity. Brigham Young was supported by a deaf and mute and a convert and a theatre was built in the early years of the settlement in Utah.

Government.—The Mormon hierarchy is highly complicated. At the apex of this system stands the head of the Church, the President, and is succeeded by Joseph Smith, jun., “Seer, Translator, Prophet”; the president is supported by two counsellors. These three are supposed to be the successors of Peter, James and John, constitute what is known as the Holy Quorom, and are the head of the priesthood of Melchisedec. Then comes the “priestric” whose chief duty is to bless and lay on hands, and after him the “twelve apostles,” forming a travelling high council. These seven, being in council, are the body of presidents over the utmost of one and three to ten, equal to the other eleven. Their duties are important. They ordain all other offices, elders, priests, teachers and deacons, lead all religious meetings, and administer the rites of baptism and sacrament. One of these is the quorum of the presidency, and acts in case the president dies or is disabled. Fourth come the seven presidents of the seventies or seventy quorums each body comprising seven presidents; these are not presidents in the sense of having executive power, but the “quorum of the first presidency,” and are the missionaries and propagandists of the body. Fifth come the high priests, whose chief duty is to officiate in all the offices of the Church in the absence of the apostles, and who are assisted by the apostles. Sixth come the priests, who are the heads of the officiating boards of each of the seven quorums, and who are styled presidents, elders and high priests. In the Aaronic priesthood, which is subordinate to the priesthood of Melchisedec, and is occupied either with temporal affairs, the highest office is that of the presiding bishop, who superintends the collection of tithes; other Aaronic officials are styled priests, teachers and deacons. The Church is made up of about 50 stakes (21 in Utah), each having seven presidents; the stake is divided into wards, which are subdivided into districts, each of which has a certain number of teachers, a meeting-house, Sunday school, day school, and dramatic, debating and literary societies.

Doctrine.—A system of polytheism has been grafted on an earlier form of the creed, according to which there are grades among the gods, the place of supreme ruler of all being taken by the primateval Adam of Heaven, who is also the highest God in polygamy, the Lord, Christ, Mahomet, Joseph Smith and Brigham Young also partake of divinity. The business of these deities is the propagation of souls to bodies begotten on earth, and the sexual relation performed by the creatures who are created in their image, and their glory is in proportion to the number of their wives and children; hence the necessity and justification of polygamy (although its practice is now not authorized by the Church), and the granting, in a state of heaven, of a body so bloated with spirit flesh that it is accompanied by the ecclesiastical ceremony of “sealing,” is forever, and is a necessary pre-requisite to heavenly bliss. A man may be sealed to any number of women, but no woman may be sealed to more than one man. Polygamy is supposed to make possible the propagation of enough bodies for thousands of spirits which have long awaited incarnation. Especially in their earlier years the Mormons believed in faith healing, and Joseph Smith bade them “trust in God when you are sick, and if you are not in the right, he will forgive you.” Their distinguishing points of faith are: religiously, a belief in a continual divine revelation through the inspired medium of the prophet at the head of the Church; morally, polygamy, though this is condemned in the Bible, is believed to be a principle divinely sanctioned, and, socially, a complete hierarchical organization. They believe in the Bible as supplemented by the Book of Mormon, the Book of Doctrine, and revelation through the president of the Church; in the gift of prophecies, visions, miracles and casting out devils; in the imminent approach of the end of the world; in their own identity with the apocalyptic saints who shall reign with Christ in a temporal kingdom, either in Missouri (at Independence) or in Utah; in the resurrection of the body; in absolute liberty of conscience; in a state of salvation for sinners, but only if they have ventured to cast themselves into the Holy Ghost by duly-authorised apostles. Among their minor beliefs is the laying down of A Word of Wisdom which is believed to have been revealed to Joseph Smith (Feb. 27, 1833), these recommendations: that it is not good to drink wine or strong drink, except at the Lord’s Supper (and then it should be home-made grape-
MORMYR—MORAY

Very little is known of the habits of these fishes. Professor G. Fritsch, of Berlin, during his stay in Egypt for the purpose of experimenting on electric fishes, observed that they perish very rapidly when removed from the water, and he had the greatest difficulty in keeping some alive in an aquarium for two or three days. Captain S. Flower has recently been more successful, and the mormyrs have proved a great success in the Gezira aquarium, near Cairo, examples of the species having lived from ten to twenty-six months. The species with comparatively large mouths feed principally on fishes and crustaceans, the others on tiny animals and vegetable and more or less decomposed matter. Delhez, on the Congo, found that many are attracted to the bodies of dead animals, and in certain underground dwellings, where they feed on the refuse thrown into the water. It is probable that the species with a rostrum use it to procure small prey hidden between stones or buried in the mud, and that the fleshy mental appendage with which they are provided is a tactile organ compensating the imperfect vision in the search for food. Until quite recently absolutely nothing was known of the breeding-habits and development. To the late J. S. Budgett we owe some very interesting observations made in the Gambia on Gymnarchus niloticus, which makes a nest, and the larvae of which are provided with filamentous external gills.

Venerated by the ancient Egyptians, the mormys are often represented on hieroglyphics and mural paintings as well as in bronze and ivory models. The early writers often mention the species in connection with the mummies, the eye of Horus, and the gill of Amun. Joseph Smith, the first Prophet, and Revelator to the Church of Jesus Christ of Latter-Day Saints (Zion, Ohio, 1835, and often reprinted); and The Pearl of Great Price: Being a choice Selection from the Revelations, Translations and Narratives of Joseph Smith, the First Prophet, and Revelator to the Church of Jesus Christ of Latter-Day Saints (Salt Lake City, 1891). The best bibliography are in H. H. Bancroft's History of Utah (San Francisco, 1899), vol. xxi. of the History of the Pacific States of North America, in which the effort to avoid bias against or for any sect or race is made; the world's best is the work biased in favour, and in I. Woodbridge Riley's The Founder of Mormonism, a Psychological Study of Joseph Smith, Jr. (New York, 1902), the first inquiry by a trained psychologist into Smith's case. More important than the previous are Linn's History of the Mormons from the Date of their Origin to the Year 1901 (New York, 1902); Linn, unlike Riley, thinks it proved that Rigdon used the companion manuscript to the report of the Baptism of Mormon. E. W. Tullidge's History of Salt Lake City (Salt Lake City, 1886) and Orson F. Whitney's History of Utah (4 vols., Salt Lake City, 1892-1898) are valuable general works on Mormonism written by men of the Reorganized Saints, Joseph Smith III and his son, C. Smith. See also J. T. Tullidge's History of the Church of Jesus Christ of Latter-Day Saints (Lamoni, Iowa, 1901); and Tullidge, a member of the same branch, wrote a Life of Joseph the Prophet (Flaxo, Illinois, and ed., 1890). Edward H. Anderson's Brief History of the State of Utah, Its People, and Their History (Salt Lake City, 1897). See also The Story of Mormonism (reprinted, 1907) are regarded by Mormons as authentic. Early attacks on Mormonism are E. D. Howe's Mormonism Unveiled (Painesville, Ohio, 1834) and Pomeroy Tucker's Origin and Progress of the Mormons (New York, 1867). Among works descriptive of Mormonism in Utah written by Gentiles the more important are: History of the Mormons: their Domestic Polity and Theology (Philadelphia, 1842), by Lient. J. W. Gunnison of the U.S.E. Army. This book took part in the preliminary to building a transcontinental railway; Utah and the Mormons (New York, 1854), by B. G. Ferris, secretary of Utah Territory in 1852-1853; Horace Greeley, Overland Journey from New York to San Francisco (New York, 1861); A Journey to Salt Lake City (London, 1861); and The City of the Saints, and across the Rocky Mountains to California (London, 1860). George F. Burton, who spent a month in Salt Lake City in 1850. There is much valuable material in the Reports of the Utah Commission appointed under the Edmunds Act, in Testimony before the Senate Committee in the Smoot case (1905-1905), and in the Report of the Committee on Privileges and Elections (Senate Report 425, 59th Congress, 1st session), also in the Smoot case.

MORMYR. The mormyrs (Mormyridae) are one of the most remarkable families of the Malacostracan fishes, confined to the fresh waters of tropical Africa and the Nile. About 100 species, referred to two sub-families and ten genera, are now known, a great number of new forms having recently been discovered in the Congo. They are curious-looking, highly aberrant fishes, very variable in the extent of the vertical fin and in the form of the head and eyes. The head, which may be either extremely abbreviated or elongated into a rostrum, with or without a dermal appendage or an "feeler." The shape of the head has suggested many of the specific names which have been given to these fish, such as elephas, tapirus, tamarind, calabalis, onis, ibis, numenius, &c. Some forms are eel-shaped. The mormyrs are further remarkable for the enormous development of the brain and for the problematic organ which surrounds it; also as being among the few fishes in which an electric organ has been discovered. This organ, situated on each side of the caudal region, is derived from the muscular system and is of feeble power; it was long considered as "pseudoelectric."
university at Saumur, which had a distinguished history until its suppression by Louis XIV, in 1683. In 1598 he published a work on which he had long been engaged, entitled De L'institution, usage et doctrine du saint sacrement de l'eucharistie en l'église ancienne (La Rochelle, 1598). A second edition, De la vie et de la mort (London, 1577), was a bridge to Charlotte Arbalæste; Traité de l'église où l'on traite des principales questions qui ont été mues sur ce point en nostre temps (London, 1578); Traité de la religion chrétienne contre les albigeois, épiscopaux, juifs, mahométains et autres infidèles (Antwerp, 1581); Le mystère d'iniquité, c'est-à-dire, l'histoire de la paix (Geneva, 1611). Two volumes of Mémoires, from 1572 to 1589, appeared at La Ferté (1624-1625), and a continuation in 12 volumes (1625); a more complete but very inaccurate edition (Mémoires, correspondances, et vie) in 12 vols. was published at Paris in 1624–1625.

See the life of Morny written by his wife for the instruction of their sons, Mémoires de Mme Duplessis-Morny, vol. i. in the ed. of correspondences de Duplessis-Morny (Paris, 1824–1825); E. and E. Haag, La France protestante, article "Morny"; J. Ambert, Du Plessis-Morny (Paris, 1847); J. Stihelin, Der Überbrüter K. Heinrichs IV. von Frankreich sur kulturfragen (Basel, 1856); Weiss, Du Plessis-Morny comme théologien (Strassburg, 1867). There is a good article "Du Plessis-Morny" by T. Schott in Hauck's Realencyclopädie, and another by Grube in Kirchenlexikon.

MORNING, properly the dawn of day, sunrise, but extended to the whole early part of the day, from the dawn to midday. "Morning" (M. Eng. mornes) was formed on the analogy of "evening," from "born," in M. Eng. morven, and originally meant the coming of the sunrise, as "evening," the coming of the close of the day (O. Eng. efnung, from afen, eve). The O. Eng. morven represents the comp. Teutonic word for the dawn, the thing which has been assigned to the root seen in "mirk," "murky," meaning to be dark, or, with more probability, to the root marh, to twinkle, shine (cf. Lith. mirga), and further to the root mar in English mar, as in Gr. χαματα, to shine (cf. Lat. marmor, marble). The M. Eng. morven dropped the n and became morn, "morrow," which properly means "morning," but was soon used of the day following the present.

The "morning-star" (Ger. Morgestern) was a military weapon of the middle ages, consisting of a mace or club with a ball head studded with spires; the spiked ball was sometimes swung loose from the head of the mace by a chain. The weapon was also known as a "holy water sprinkler." The "morning-gift," earlier "morveye," Ger. Morgengabe, was the present given to a bride by her husband on the morning after the marriage. The custom is probably connected with the origin of the term "morganatic marriage" (see MORGANATIC).

MORNY, CHARLES AUGUSTE LOUIS JOSEPH, DUC DE (1811–1865), French statesman, was the natural son of Hortensia Beauharnais (wife of Louis Bonaparte, and queen of Holland) and Charles Joseph, comte de Flahaut (q.v.), and therefore half-brother of Napoleon III. He was born in Paris on the 21st of October 1811, and his birth was duly registered in a certificate which made him the legitimate son of Auguste Jean Hyacinthe Demoroy, described as a landowner of St. Domingo. M. Demoroy was in fact an officer in the Prussian army and a native of St. Domingo, though he owned no land there or elsewhere. After a brilliant school and college career he received a commission in the army, and next year entered the staff college and became lieutenant. The comte de Morny, as he was called by a polite fiction, served in Algeria in 1834–35 as aide-de-camp to General Camille Alphonse Trezel, whose life he saved under the walls of Constantine. When he returned to Paris in 1838 he secured a solid position in the business world by the establishment of a great beetroot-sugar industry at Clermont in Auvergne, and by writing a pamphlet Sur la question des sures in 1838. In these and other lucrative speculations he was helped by the beautiful and wealthy wife of the Belgian ambassador, Charles Joseph, comte Lehon, until there were few great commercial enterprises in Paris in which he had not an interest. Although he sat as deputy for Clermont-Ferrand from 1842 onwards he took at first no important part in party politics, but he was heard with respect on industrial and financial questions. He supported the government of Louis Philippe, because revolution threatened his commercial interests, but before the catastrophe of 1848, by which he was temporarily ruined, he mediated conversion to the legitimist cause represented by the comte de Chambord. His attitude was expressed by the mot with which he is said to have replied to a lady who asked what he would do if the comte de Chambord were at the head of the state: ""Hang myself on the side of the broom handle," was his answer. Presently he was admitted to the intimate circle of Louis Napoleon, and he helped him to engineer the coup d'état of the 2nd of December 1851 on the morrow of which he received the ministry of the interior. After six months of office, during which he had shown commendable moderation and tact to his political opponents, he resigned his portfolio, ostensibly because he disapproved of the confiscation of the Orleans property but really because Napoleon, influenced by Morny's rivals, resolved his pretensions to a foremost place in the government and his desire to insist on his claims as a member of the Bonaparte family. He now resumed his financial speculations, and when in 1854 he became president of the Corps Législatif, a position which he filled with consummate dignity and tact for the rest of his life, he used his official rank to assist his schemes.

Politics and high finance with Morny went hand in hand. In 1856 he was sent as special envoy to the coronation of Alexander II. of Russia; he executed his mission with prodigal splendour, and brought home a wife, Princess Sophie Troubetzkoj, who and her connexions greatly strengthened his social position. In 1862 Morny, whose power was at its culminating point, was created a duke. It is said that he aspired to the throne of Mexico, and that the French expedition sent to place Maximilian on the throne was prompted by Napoleon's desire to thwart this ambition. In any case, in spite of occasional dissensions, Morny's influence with the emperor remained very great, and the liberal traditions which he had retained enabled him to serve the imperial cause by his influence with the leaders of the opposition, the most conspicuous of whom, Émile Ollivier, was detached from his colleagues by his efforts. But while he was laying the foundations of the "Liberal Empire" his health, undermined by a ceaseless round of political and financial business, of gaiety and dissipation, was giving way, and was further injured by indulgence in quack medicines. The emperor and the empress visited him just before his death in Paris on the 10th of March 1865.

Morny's valuable collection of pictures was sold after his death. In spite of his undoubted wit and social gifts Morny failed to secure the distinction he desired as a dramatist, and now his pieces which appeared under the pseudonym of M. de St Rémy—Sur la cause de France; Monseigneur Choufleur y restera chez lui, and the Finesse du mari among others—met with any considerable success on the stage.

The figure of the duc de Morny is familiar to the general reader in the duc de Mora of Le Nabab d'Alphonse Daudet, who had been one of his secretaries. See F. Lollis, Le Duc de Morny et la société du second empire (1900). Earlier accounts are by H. Castile, M. de Morny (1859), and Arthur de la Guêneresse, Études et portraits
politiqes (1856). See the literature dealing with Napoleon III., and the article on Flahaut de la Billaderie; also F. Lolié, Le Duc de Morny, adapted by B. O'Donnell. A volume, Extraits des mémoires de Morny: Une Ambassade en Russie 1856, was published in 1892.

MORO, ANTONIO (c. 1512-1575), otherwise known as Sir Anthony Mory, the eminent portrait-painter, was born at Udine in the Suevian Moro, in 1525 according to Karl van Mander in his Het Leven der Schilders. He studied his art under Jan Schoorel; and after making a professional visit to Italy he commenced to paint portraits in the style of Hans Holbein. His rise to eminence was rapid. In 1552 he was invited to Madrid by the emperor Charles V. to execute a likeness of Prince Philip. Two years afterwards he was in London painting the portrait of Queen Mary. For this picture he received an annual salary and, as some suppose, the honour of knighthood were conferred upon him. On the death of Mary in 1558 Moro returned to Spain, and there lived for two years in great honour with Philip II., executing, in addition to portraits, several copies after Titian. His death took place at Antwerp about 1575. Among his figure-pictures Van Mander specifies the "Circumcision of Christ," executed for Antwerp Cathedral, as one of the most notable. His portraits are full of individuality, and characterized by firm and solid rendering of flesh. Several admirable examples are preserved in Madrid; among the rest the portrait of Philip II., which is exceptionally well executed by Milles (L'Art, Dec. 8, 1878). "Moro's style," says Stanley in his Dutch and Flemish Painters, "so much resembles that of Holbein as to frequently create a doubt as to which of them a portrait is to be attributed; but he is not so clear and delicate in his colouring (perhaps from having painted so much in Spain) as that master."

MOROCCO (EL MAGHERIL EL AKSA, "The Farthest West," i.e. of the Mahomedan world), an independent state of North Africa, bounded on the N. by the Mediterranean, on the E. by Algeria, on the S. (indubitably) by the Sahara, and on the W. by the Atlantic as far south as Wad Dra'a. Its landward limits can only be vaguely defined. The eastern frontier towards Algeria, determined by the treaty of 1844, is a purely conventional line starting from the mouth of a small stream called the Skis and running across country in a general S.S.E. direction. In 1900 this was given a westerly trend to the south by the treaty of the Atlas by the Figig, Igil and Tuit oases by France. The southern boundaries extended and are now accepted according to the treaties of 1880 and 1892. The central authorities, Behn and Wagner, who included Figig, Tuit, Kenatsa and other oases, estimated (in 1882) the then area of the sultanate at 305,548 sq. m. The allegiance of many of the tribes within this compass is questionable and intermittent, and the loss of the district from Figig to Tuit, which is not accurately defined, has considerably reduced the area. Morocco is still the portion of Northern Africa about which European information is most defective, and all maps are still to a considerable extent composed of uncertain material eked out by probabilities and conjecture.

The Mediterranean Coast Lands.—The seaward aspect of Morocco only is known in detail. To the Mediterranean it presents for about 200 m. the rugged profile of the Rif hills (still unexplored), which form the western part of the Central Anti-Atlas; beyond them is a sweeps of sandy beach, but occasionally open up into beautiful and fertile valleys. About 6 m. west of the Skis lies the mouth of the river Mulwiya; and 10 m. farther on, opposite Cape del Agua (Ras Sidli; Bahlaniya), a deep of the Spanish archipelago, named by Spain as Chaffarinas or Zayar Zafran (Spanish las Chafarinas), which protect the best roadstead on the Rif coast. Between Point Quiviuna and Mellila runs a low and sandy shore in front of a great sand dune, which forms the upper end of the most beautiful valleys in the Rif, clothed with verdure and dotted with hamlets. A Spanish presidio occupies one of the larger of the Alhucemas (el-Malama), which are identified with the Ad Sex Insulas of the itineraries. Another Spanish presidio crowns the island rock of Peñon de Velez; and in the valley off which it lies stood a town known to the Spaniards as Velez de Gomera, to the Arabs as Baddis, which continued to be a place of importance in the 16th century. The so-called Bay of Tetuan (Tehtawian) —the town is just visible from the sea—is little more than the straight stretch of coast between Cape Mazari on the south and Cape Negro or Negrete on the north, with the coast town of Tetuan, which commands the only headland gives an appearance of depth. From Cape Negro northwards to Ceuta the most notable object is the summit of Jebel Músa, which, though situated on the Strait of Gibraltar, towers above the intervening hills. To the sierra of Kasba, 22 m., the only stretch in Morocco, occupies a peninsula—the head, Mt. Achi, extending about 4 m. out to sea, and the neck being low and narrow. It marks the eastern end of the strait. Westwards, the first point of landward is the ancient Jebel Músa, the Elvases of Strabo, and the Apes' Hill of English chroniclers. Southward from Angad, the only port with a fixed intermittent white light, visible for 36 m. The Atlantic Coast Line.—The Atlantic coast of Morocco is remarkable for its regularity; it has not a single gulf or noteworthy estuary, and is bounded by a group of dry and barren islands, off which the Spanish Revenge, according to Von Behm (El Sahara, 1856), and the Island of Qrata, with a population of about 1200. For the next 16 m., between Azila and Laraïch (Larache), the coast has a tolerably bold background of hills, Jebel Sarsar forming an important landmark for the latter part of the coast, with its flat summit, Roman and medieval remains, is historically one of the most interesting places in Morocco. A line of reddish cliffs about 300 ft. high runs south for about 10 m. from the W. Lekkus, at whose mouth the town is built; then the coast sinks till it reaches the shrine of Mulla Bîl塞imán on an island termed Om El-Mukhamar (so-called "Old Mâmora"), and a similar height crowned by the tomb of Sidi 'Abd Allah Jâlî lies the outlet of the Blue Lake. (Marja Zarka), 10 or 12 m. long. Farther south, and separated from the land by a narrow channel, lies the island of Dakhla, which is more extensive lagoon of Ras Ed-Dûra, which in the dry season becomes a series of marshy mires, but in the rainy season fills up and discharges into the Sefib. Eastward it is connected with the sea by a narrow channel opened by Spaniards, known as the outlet of the Scibâ lies Mehdîiya (otherwise misnamed New Mâmora or Mehdisma) formed by 'Abd el-Mînim, and named after the Muwâbâdi Mahdi. It was held by Spain from 1614 to 1681. Perhaps the most interesting point is the cape of Methýa (N. end of Cape Tifjîhit), where the Sultan of Morocco has a seat and the spot where the Muscovy ships (1670 and 1772) and Dâr el-Baida or Casablanca, it runs in a straight line west south-west. Azamur (Berber for "The Wild Olives," viz. of the Sheikh Bû Shalîb)—once the frontier town of the kingdom of Fez and the site of the Spanish fort—and a spot on the line of the Um er-Râbi'a river a line of hills skirts the sea; the shore is for the most part low, and, with the exception of cliffs at Fedala (a small village, originally a port, partly rebuilt by Mulai Isâîlî, and south to Cape Gibr (Jebel Uthayt, the designation of Jebel Ida à Tanân, a spur of the Atlas. Beyond this headland lies Agadir (Agadir Ighir), the Santa Cruz Mayor or Santa Cruz de Berbería.
of the Spaniards, formerly known as the Gate of the Sudan. It is a little town with white battlements three-quarters of a mile in circumference, on a steep eminence 600 ft. high. In the 16th century it was seized by the Portuguese; but in 1536 it was captured by Mulai Ahmad, one of the founders of the Sa'di dynasty. Some 60 m. farther south, at the mouth of a river known by the same name, is the roadstead of Massa, with a mosque popularly reputed the scene of Jonah's restoration to terra firma. This port was regularly visited by the Genoese traders in the 16th century, who exported skins, gum, wax, gold and indigo. Another 50 m. farther south lies Ilini, a landing-place easily recognizable by the shrine of Sidi Wotzek, a few miles to the south of which is the Cape Nūn of the Portuguese. The better known Cape Nūn lies 5 or 6 m. north of the W. Nūn, at the mouth of which is Assāka, a port which the sultan of Morocco opened to foreign trade in 1882, but closed after six months. From Assāka to the mouth of the Dra'a the country continues broken and fertile, but farther south it is flatter and more sandy, so that with the Dra'a the Sahara may be said to begin.

Character of the Interior.—The backbone of the country is the Great Atlas (Dāren of the Berbers), for which see Atlas. The principal rivers take their rise in the Atlas Mountains, and the headwaters of the Mulwiya, the Sebū, the Um er Rabiba, the Dra'a and the Zīz all rise between 30° 20' and 32° 30' N., and between 25° 10' and 5° W. The Mulwiya (Mulucha and Malva of Pliny, &c.) is the river which the French have long wished to make the western boundary of Algeria. Its course is largely unexplored save by native French officials. About 34° 20' N., General Colvile found it some 200 yds. wide but quite shallow; about 25 m. east of its source, where it is crossed by the route to Ziz, it is already a powerful stream with a deep bed cut in the granite rock, and shortly afterwards it is joined by the W. Sgimmel, a still larger affluent (Roßfs). Of the lesser streams which flow into the Mediterranean it is enough to mention the W. Martil or Martin (otherwise W. Bū Sīha, W. Ras, W. Mejeka), which falls into the Bay of Tetuan, and is identified with the Tamuda of Pliny and Thaluda of Ptolemy.

On the Atlantic seaboard there are a number of comparatively small streams north of the Sebū, the chief of which is the winding W. Lekkus, with several tributaries. The Sebū (the Subur magnificus et navigabilis of Pliny) may be compared to the Thames in length and width, though not in steadiness and depth of current. At Mejera'at al-Kafr, about 70 m. from its mouth, it is about 10 ft. deep in the month of May and more than 460 ft. wide; and, though its banks are 21 ft. high, extensive inundations occur. The tide ascends as far as El-Kanṭara, 15 m. above Ma'mora, and steam barges with a small draught of water could make their way to the ford just mentioned, and
possibly even as far as Fez. Affluents of the Sebû are W. Mlikkes and W. Redem (90 m. long). The swift and muddy current of W. Beh特 usuallyロts itself in a swamp before it reaches the main stream. The Râbtagg, which debouches between Rabat and Salli, is about the same length as the Beh特, but of much more importance. It and the Usr el-Rajib of the mother, although their mouths are widely separated, drain the northern slopes of the central Atlas. The impetuous Usr el-Rajib, with a rocky bed and many rapids, is perhaps as large as the Sebû. W. el-Abâib, W. Akhdar and W. Tassult are the principal affluents. This last is separated by about 10 m. from the valley of the Tanât, the river which flows to the north of the city of Marrêkesh; and by the W. Neffis, the Asl el-Mal (Asil is Berber for river), the W. Usbi, and other smaller tributaries, receives the waters of about 180 m. of the Atlas range.

The valley between the Atlas and the Anti-Atlas is traversed by the W. Sûs, whose ever-flowing stream is sufficient to turn the whole district into a garden. The Mûar or W. el-Mounâb of the valley headwaters drain only one or two of the lower valleys at the southwest end of the Anti-Atlas, is “about 50 yds. from bank to bank, at the mouth, with a depth at high water and in the proper channel of something over a fathom.” Farther south is the Assâla, known to European geographers as the W. Nûn; and finally the W. Draâ is reached, which in length exceeds all the rivers of Morocco, but, except in spring, when the snows are melting in the highlands, remains throughout its lower reaches a dry sandy channel. In the upper valleys however innumerable streams from the south side of the main chain of the Atlas, the W. Dâdès from the east, and the Asif Marghen, W. el-Molah, or Warrazet from the west, flow through populous and fertile valleys, and uniting to form the Draâ cut their way southward through a gorge in the Jebel Soghar, which, as the name implies, is a lower range running parallel to the Atlas proper. For the next 150 m. the stream holds S.S.E., drained at every step, traversing canals which regulate the supply, till at last its dwindling current bends westward to the sebkha (salt marsh) of Debâya. For a few weeks once a year the thaw-floods fill this shallow but extensive basin and rush onwards to the Atlantic; but in summer it dries up, and, like the bed of the river for some distance below, is covered with flourishing crops. From the south of the Atlas still farther east descend other streams, the W. Ziz (with its tributaries the W. Todgha and W. Gheris), the W. Ghfira, the W. Kenatsa, &c., which, after watering the oases of Medghara, Tafîfâl (Sajilmâsa), Kenatsa, &c., lose themselves in the sands of the Sahara.

Geology.—The Atlas Mountains, which are built up of a series of ridges rising to 12,000 ft. to the east of Morocco, form the backbone of the country. The central and highest portions consist of slates, crystalline limestones and schists of Archean, Pre-Cambrian and post-Cambrian ages, and are traversed through by numerous intrusions of basalts and diorites. The mass of Jebel Têzah is composed of mica-schists and porphyries which appear to bear closer resemblances to the metamorphic rocks of Egypt and of the Anti-Atlas than to the gneisses of the rest of Morocco. The strata of the central ridges are succeeded by a great thickness of purple marls, red sandstones, conglomerates and calcarceous rocks, occurring in faulted, folded and detached areas and recently considered as beds of marine origin. The upper limestone of Devonian and Carboniferous ages also form a broad zone extending into the Sahara on the south and south-eastern flanks. The whole of the Cretaceous system is represented by the shales and lime- stones occurring between the coast and the edge of the plateau above Morocco, but do not enter into the composition of the High Atlas.

Moraines, made up largely of unstratified blocks of porphyry, have been reported from the Upper Atlas. At the foot of the mountains, extensive sheets of boulder clays have been observed. The millstone-size and were considered by Maw to belong to the Glacial Epoch. Between Damnut and the sea, however, the signs of a former glaciation appear to be insignificant. No moraines occur here, and consequently the glacial origin of the boulder beds described by Maw has been questioned. The moraines were probably alluvial cones brought down from the High Atlas and mountainous regions. From Mogador to 60 m. inland, and over the plains around Marrêkesh, a tufaceous deposit forming a hard crust, several feet thick, follows every undulation of the ground. Immense accumulations of tufa are met with in the limestone areas of the mountains. The chief tectonic structures which trend N. 20° E. belong to the Alpine and Mediterranean systems. The Cretaceous and Tertiary rocks are involved in these movements, which, however, were moulded on an earlier folding affecting the palaeozoic rocks of the Atlas region. The sunning of Africa from Europe at the Straits of Gibraltar took place in large part during the time of the Barbary coast to a height of 50 to 70 ft. of recent date.

Climate.—The climate is good, and produces a hardy race. Shielded by the Atlas from the hot winds of the Sahara, the coast is often considered the most pleasant and healthful part of the country. Tangier is of course free from the more extreme manifestations of desertic conditions, and Mogador and Rabat and RAGRAK, as they are called, receive the southern desert winds, or sharti, otherwise dry and somewhat trying to invalids. The wonderfully temperate climate of Mogador is due in a great measure to trustworthy trade-winds. In Tangier and Mogador the true Mediterranean type of climate prevails: though the winds from the west, or sharti, otherwise dry and somewhat trying to invalids. The wonderfully temperate climate of Mogador is due in a great measure to trustworthy trade-winds. In Tangier and Mogador the true Mediterranean type of climate prevails: though the winds from the west, or sharti, otherwise dry and somewhat trying to invalids.

Fauna.—The absence of woodland keeps wild animals in检查. Besides the lion, which exists in very limited numbers — and, according to local proverbs, with diminished courage—the spotted leopard, panther, hyena, fox, and the wild dog are common. Among birds the eagle, buzzard, partridge, and gazelle are the most important. The addâd or wild sheep is found in the more inaccessible parts of the Atlas. Rabbits swarm in the country to the north of the Bâtagrag, and since 1870 they have been introduced in the region of Tangier, where wild hares are generally common. Rats are from time to time a plague to agriculturists, and the jerboa is frequently met with. A kind of ground-squirrel, the stôi, occurs in the southern provinces. Mammals which are common in the same region are the antelope and the wild ass, the houbara of Jebel Mûsa or Apes’ Hill. The common wild birds include blackbirds, goldfinches, linnets, greylins, robins, wagtails, skylarks and crested larks, swifts, magpies, cuckoos, lapwings, rollers, storks, and particularly the harrier, and the Bédouins have called backfisted egrets. The house-sparrow is not found; between Marrêkesh and Mogador its place is taken by a beautiful bird (Emberiza striata), locally called tabb, or “doctor.” The birds of prey include eagles, owls, kites, falcons, and hawks, and the larger birds of prey and the water-fowl. The Barbary partridge is the main resource of the Bédouins and the native housewife; the other species of partridge, bustards, guinea-fowl, plovers, grouse, snipe, quail, curlew, ducks and other water-fowl. Among the coast there is lack of gulls, gannets, pelicans, flamingoes, herons, whimbrel, oyster-catchers, &c. Most towns have their colony of storks. Several venomous snakes and two vipers are found, but are not common, and the same may be said of scorpions and tarantulas, but centipedes are more numerous. Human parasites are, however, most to be guarded against. The Moroccon, for instance, has an everlasting craving for human flesh. Insects are more numerous, and the goats, which furnish the famous leather, need even less care are still more abundant. Domestic fowls are kept in great numbers; they are of the Spanish type, small and prolific.

Tangier and Mogador are the sources of the anchovy and tuna, and Tangier attracts fishermen from Spain, Portugal and other parts of Europe. Occasionally a small shoal may be found far south as Mogador. Soles, tarbot, bream, bass, conger eel and mullet are common, but as a general rule they are not large. A curious fish is the sole-bodied large fish called the asînîmah (scena aquila), rough scaled and resembling a cod, and the tasaqâli (Tremnomon salator), the “blue fish” of North America. Crayfish, prawns, oystreed, and cuttle fish are common in the coast as well; there is no proper method of catching them, and edible crabs seem unknown. The tunny, piperch, sardine, and anchovy are much smaller than in the Mediterranean饲, and the Babbar shrimp "is a great industry on the principal rivers of the coast, and vast numbers of the fish, which are often from 5 to 15 lb in weight are dried and salted. They ascend from the sea in spring. Barrels
and a few other small fish swim in the streams, but for the angler there is little real sport.

Flora.—From the presence of a large proportion of plants of central and northern Europe (none of the northern plants, however, being of alpine or arctic type) and the absence of southern types, the flora of the Moroccan flora is altogether a portion of that great Mediterranean flora which, with local peculiarities, one finds from the Indus to the Atlantic Islands, and that the mountain flora of Morocco is a southerly extension of the flora of the Atlas, and that this flora is the admixture of extraneous elements, but so long isolated from the neighboring regions that a considerable number of new specific types have been developed. Of the individual plants none are more curious than the typical sequoia, Sequoiadendron aralid (Eng. and Shaw) or sequoia quadrivalvis, or Thuja articulata of Shaw) is a cypress-like tree that grows on the Atlas both in Morocco and Algeria. It furnishes gum sandarac; and its beautiful and enduring timber has been in demand for a long time. The leaves of the nova isthmus, as it was named, was roofed, and with the citrus-wood, arbor vitae, of the ancient Romans. The argan, Elaeodendron argan (Argania sideroxylon) is confined to a tract of country extending about 150 m. along the coast, from the river Tanif to almost the Sahara, and abundant in it; and it is found nowhere else in the world. The fruit, which ripens between May and August, is an olive-looking nut, greedily eaten by camels, mules, goats, sheep, and horned cattle (not by horses) for the sake of the fleshly pericarp, and crushed by them to get the kernels. The brown seed husks have a strong and fulsome savour" renders it nauseous to the European palate, this oil is largely used in the cookery of southern Morocco. The prickly pear and the aloes form part of the features of the landscape of the plains. They are very important, the prickly pear is neither indigenous. The cork tree has lost ground enormously, though it probably forms the staple of the Ma'mora forest, which extends for some 20 m. between the Bb Ragrag and the Sub. The palm trees are also abundant, the so-called date-palm, which has been planted on the plains is the thorny lotus or mimosa; in the mountainous regions it is reduced to a mere scrub. Lenticels, arbutus, oleanders, junipers and broom are also common, but vast stretches of country are covered with scrub (or sherd). The melon or apricot (both white and sour), apricots, plums, melons, mulberries, walnuts and chestnuts are common in many parts. Tentu and Larash are famous for oranges. Mequezn for quinces, Marrakesh for pomegranates, Fez for the dates, while in most places the melon is the almost exclusive vegetable. Peas, Tagodast, Edanan and Rabat for grapes and Tarundat for olives. The grape is extensively cultivated, but principally for eating; the Jewish manufacture crude but palatable wines. Sugar, once grown in Sús, to supply the demands of the whole of Morocco, has disappeared, grape-sugar is now imported. Inland towns and cities are cultivated under the restrictions of an imperial monopoly—the former (of quality) being largely used as hashish, the latter, though never smoked, as snuff. Barley is the most usual cereal; but wheat is also grown. Inset vegetables, such as potatoes, peans and canary seed are also obtained. Tomatoes, tomatoes, cabbages and beets have been introduced from abroad; otherwise the ordinary vegetables are peas, beans, turnips, onions, garlic, capucin, cucumbers, melons, zucchini, carrots and beets are all grown. The latter are extensively grown, for use in cooking and in the preparation of tea.

In some of the Atlas valleys there is a wealth of timber, enormous conifers, 10 to 12 ft. in girth of stem, oaks, etc., but the greater part of the coniferous forest, has been cleared of forest, exhibiting only bushwood, and the lesser fruit-trees. Cowan, writing more immediately of the country between Morocco and Mogador, speaks of "drifts of asphodel, white lilies, blue convolvuli, white flower brooms, thyme and lavender". Cooper, among those "herb thistles, colossal daikon and poppies"; and Trotter tells how "few miles the undulating plateau of Kasar Fará'ín was covered with wild flowers, whose varied colours, and the partiality with which each species confined itself to certain ground, gave to the landscape a brilliant and unique appearance." During the month of June, the wild flowers are "occurred in patches an acre in size; farther on, wild hills and valleys were of a delicate blue tint from convolvulus and borage. At times the traveller's tent is pitched on a carpet of mignonette—"indicating the universal distribution of the cereifera; the cereifera color one can well imagine that the Moors drew the inspiration of their characteristic art; but the season of flower splendor is brief, and under the hot sun everything soon sinks into the monotony of straw.

Inhabitants.—No well-founded estimate exists as to the number of inhabitants within the Moorish Empire, and the suggestions that the botany of Morocco has been explored by Balansa (1867), Hooker, Bal and Maw (1871), Rein and Fritsch (1873), Ibrahim Ammerib (a Berber collector, 1873, 1876), the Rabbi Mardochée Abi Serur (1872-1873); and the results have been systematically compiled in Coelho's Monographie: Flora atlanticae: en Flore des bois barbaresques (Paris, 1881, &c.)

Vary between five and ten millions. The majority of the inhabitants are pastoral and agricultural in their pursuits; but while large stretches of country are inhabited sparsely or not at all, other parts, especially along the Atlas slopes, are closely dotted with considerable villages whose hardy occupants cultivate every foot of level surface which it is possible to till and irrigate. Three races inhabit Morocco, and the members of two others are continually being introduced. The most numerous and important are the aboriginal Berbers (q.v.)—known locally also as Amazigh—who inhabit the mountainous districts, and whose blood to a greater or less extent permeates the whole population. These were the people who thirteenth conquered Spain—only from the Visigoths, and twice from their less stalwart co-religionists. It has been its constant reinforcement by this Berber element that has maintained the independence of Morocco alone among the countries of North Africa. The plains are for the most part occupied by Arabs (q.v.), introduced in the 7th and 8th centuries, long after the so-called "Arab invasion" of the 7th century, which would have left few traces but for the Moslem missionaries who came after them. A recent large number of the plainsmen are, however, composite Arabized Berbers, known to foreigners as "Moors" (q.v.), to which division also the mixed race of the towns belongs. The Moors are never found in the mountains save as religious teachers or authorities, but only a small proportion of them continue nomadic.

The third race which may be considered native is the Jewish, consisting of two distinct sections: those settled among the Berbers from time immemorial, speaking their language, and in addition a hideously corrupt Arabic; and those expelled from Europe within comparatively modern times, who have got little farther than the ports, where they speak Spanish with the addition of Arabic. These latter are the most progressive and florishing of all the inhabitants of Morocco, and in their hands is much of the foreign trade. It is a remarkable fact that several of the so-called Berber tribes are believed to have been of Jewish origin, having embraced Islam in the coming of Mulai Idris. To these white races constant additions of a negro element are being added by the slave-trade with the western Sudan, while inter-marriages between negro and Arab or Berber have produced a proportion of mulattos.

The last class consists of the small colonies of Europeans settled at the ports, for the most part engaged in trade. The largest of the colonies is the case principally Spanish, is found in Tangier. All such foreign and Moorish subjects are under the jurisdiction of their own consular courts. They possess, moreover, the right of claiming the protection of their authorities for natives entrusted with their interests, without which, in the absence of justice, commerce with the interior would be impossible.

Language.—The language of Morocco is Berber, of which several dialects are spoken, notably that of the Rif, towards Algeria, and the Shilha of central Morocco and the Sús. Of these very little is known; but they do not essentially differ from one another or from those of Algeria. Nevertheless, the Moorish language is of Arabic origin, and a varying proportion of Arabic or other admixtures, there being no written standard to maintain. On the plains and coast of central Morocco, however, Arabic has superseded Berber, as the language of the inhabitants. In the south, when Idrís ibn Khaldún found the Arabic of Morocco very corrupt, it has made great strides, and having always been a foreign tongue with the Korán as its model, it has escaped many of the faults into which Eastern Arabic outside Arabia has fallen. This is especially noticeable in the correct Arab value given to the alphabet and in the strictly classical use of many terms, especially among the litterati of Fez.
MOROCCO

There are only three great inland cities, each of which in turn serves as metropolis: Fez, Mequinez and Marrakesh. The towns next in importance are the seaport of Tangier, Casablanca (Dar el Baida), Mogador, Mazagan, Safi, Sali-Rabat, Larache and Tetuan. All of these have grown mainly not by the hands of colonists, but rather by the activities of tapsir, that is, of Muslim tribes who, with their families and the whole of their cattle, have migrated to the new lands. The ports of Asmuhm and Azila being closed to trade, are in a decayed condition. On the Mediterranean shore, along the coast of Er-Rit, the Spartians have for centuries possessed Ceuta, Peon de Velez, Allucomas and Melilla; in 1848 they appeared to have entirely mastered the situation, but in the 1850s Azila was only of local importance. The towns of Mulai Idris, Zarhûn, Sheshâwân and Wazzân (the last-named of which is open to Europeans), and the minor towns of Al Kâsar, Sifrí, Tâza, Dibû and Ujdâ in northern Morocco (once the kingdom of Fez); Dammât, El Klî, Sefí Râhal, Zanzan and Amsud in central Morocco (once the kingdom of Marrakesh); Tarudant, Ilgh, Tiznit and Gilmân in southern Morocco (once the kingdom of Sûs).

The town of Mulai Idris Zarhûn lies to the north of Mequinez. James Jackson, who in 1801 managed to pay a hurried visit, is the only European known to have entered its gates. It is placed at an altitude of approximately 1500 to 2000 inhabitants, compact, and with several large but not well-paved streets. The streets of Tangier are not lined with houses, but are open to European visitors, which Sheshâwân (or Sheshâwan), another sacred city of shariâf, founded in 1471, day's ride into the mountains south of Tetuan, is not. Sifri is pictureque scenery, and the gates of the town are open to visitors on foot and are walled.

The population, in Leo's time 20,000, is now 50,000, of whom 800 are Jews. Dibû, to the east of Tâza, is a small but important Jewish community. About 1 km from the city of Táza, is the town of Sidi Mulai Idris, that is, Svti Mulai Idris, which is open to European visitors, which Sheshâwân (or Sheshâwan), another sacred city of shariâf, founded in 1471, day's ride into the mountains south of Tetuan, is not. Sifri is pictureque scenery, and the gates of the town are open to visitors on foot and are walled.

Vast plains of the country are traversed by the river Ramâna, which winds its way northward through the great plain of Temara, and then turns eastward, flowing into the Mediterranean Sea. The region is one of the most fertile in the country, and is an important center of agriculture. The river is navigable for most of its course, and is crossed by a number of bridges. The surrounding countryside is characterized by rich agricultural land and fertile grazing areas. In the north, the plains give way to the Atlas Mountains, which are rugged and mountainous. The region is known for its scenic beauty and agricultural productivity.

The town of Tangier, located on the coast, was once a major trading center and a gateway to the interior. It is situated on a hill overlooking the bay, and is surrounded by a wall with battlements. The town has a long and storied history, and was a center of commerce and culture for centuries. The surrounding countryside is characterized by rich agricultural land and fertile grazing areas. with altogether by dishonest practices, many arising out of the long credit in vogue.

Government.—The Moorish government is a limited autocracy, the theoretically absolute power of the sultan being greatly circumscribed by the religious influences which in a measure support him, and by the official proletariat with which he is surrounded. The central government is known as the maghzen or makhzan (an Arabic word primarily meaning storehouse), a term also applied to the whole administrative body and collectively to the privileged tribes from whose ranks the state officials are recruited. At the head of the administration are the wazirs or ministers of state, who possess no power independent of the sultan's will. The wazirs in general accompany the court, but the minister for foreign affairs is stationed at Tangier. Local administration is directed by the governors of provinces and towns, who are nominated by the wazir el-dakhâlî (minister of the interior). The subordinate town officials are appointed by the governor, and shelds direct the affairs of the villages. All appointments are practically without pay, office holders being expected to obtain remuneration from "presents," i.e. bribes and extortion. Attached to the government service are a number of tribes (called maghzen tribes), who furnish the sultan's body-guard, garrison certain towns, and perform other duties in return for exemption from taxation. There was no regular assessment for taxation, but such organized spoliation as might be required for public or private ends. That part of the empire where the sultan's authority is supreme is known as blad el-maghzen (government country); those regions where the sultan's authority is precarious are called blad es-siba (the unserviceable country).

All the powers are represented in Tangier by diplomatic and consular officials, whose independent jurisdiction over their respective fellow-subjects leads to the frequent confusion of justice. The civil and ecclesiastical courts are not often held in Moorish courts, where venality reigns, and unprotected Jews suffer constant injustice, besides daily indignities, for which they repay themselves by superior astuteness.

Army.—A half-organized army—service in which is partly hereditary, partly forced—is periodically employed in collecting taxes at sword-point, and in "eating up" the provinces; with it the custom is (or was) for the sultan to go forth to war each summer, spending the winter in one of his capitals. The only approach to a regular army consists of certain hereditary troops furnished by the maghzen tribes, the Bohhrâ' (black), the Udâfâ (mulatto), the Ashragh and Atrash, being the chief tribes, and the Calis, who draw their bulk from Makhâmzâna (mixed), all of whom are horsemen. The infantry (Askâriya) are mostly rough levies; only a small portion being well trained under European officers. No accurate estimate can be formed of the able-bodied men, as the arms are of every pattern. There is no navy, but the government possesses several small steamers, one or two mounting guns.

Religion.—The religion of Morocco is Islam, the Moors being among the strictest followers of Mahomet. The divisions of the East are unknown, and their tenets include the traditional tenets of the Chosra or Shias and Sunnis, but, as employing the Mâleî ritual, they must be classed with the latter. Recognizing their own sultan as Amir el-Mouminin ("Commander of the Faithful") and Khalifa of God on earth, they acknowledge no other claimant to that position, and have had few dealings with the Turks, whom they consider corrupt. They have not yet given way extensively to strong drink.

Mission.—The Franciscans for six or seven centuries have labored in the cause of missions; in the order of the Church for that task in 1214, and many of them, including several British and Irish missionaries, suffered martyrdom; but they have abandoned attempts to convert the Moors. The London Jewish Society publishes their translations and since 1883 various Protestant agencies support a considerable number of missionaries, men and women, including doctors and nurses.

Education.—The level of education could hardly be lower, although most of the Moorish youth has the opportunity to study and read or write. Only traders trouble about schools, and even their curiosity is not always sufficient to make them keep to their studies. Young men who wish to pursue their studies attend colleges in Fez or elsewhere to acquire some knowledge of Mahomedan theology, logic, and jurisprudence.

Literature and Travel.—Journalism is entirely foreign, and was introduced in 1883, at the same time as the printing-press, Spanish, French and English newspapers being established in quick succession. The sultan el Hasan III, set up a lithographic establishment in Fez, from which a valuable series of Arabic theological, legal and historical works have been issued, but most noteworthy of all is the publication in Cairo in 1895 of an Arabic history of Morocco, in four volumes, by a native of Salli, Ahmad bin Khalid en-Nâsîri. A most practical step was taken by the French, on the conclusion of the agreement with Great Britain in 1904, in the establishment of a state-subvention Mission scientifique au Maroc, which, in addition to establishing at Tangier the only public library in the empire, engaged a number of able students in research work, which was afterwards published in the periodical publications Archives marocaines (6 vols., 1904–1906) and L’Afrique française.

Other forward steps have been taken in the production of several important volumes on the country and in serious attempts to explore the Atlas. The vicomte de Foucault attained the first place by his intrepid journeys as a Jew through the forbidden regions and by his workman-like geographical records; Joseph Thomson did good work in the Atlas, though within a limited area; the vicomte de la Martinière excavated some of the Roman remains; Mr. Walter B. Harris made a bold journey to Taflâlit; and the marquis de Segonzac and Louis Gentil added to the knowledge of the Atlas by interesting expeditions. A hydrographic mission under A. H. Dyé also did valuable work (1905–1909). An equally important service was rendered by the compilation by Sir R. Lambert Playfair and Dr. Robert Brown of an invaluable Bibliographie of Morocco to the end of 1883 (1893), containing over two thousand entries.

History.—The prehistoric antiquities of Morocco are of considerable interest. In the cave at Cape Spartel Tissot found regularly shaped arrow-heads, and in the north of the country he met with dolmens, barrows and cromlechs, just as in Algeria or Tunisia. The dolmens usually form a trapezium, and the body seems to have been buried with the knees drawn up to the chin. At M'zorah, a quaint little village of widely-scattered houses built of rough blocks of yellow soft sandstone, about 8 or 10 m. south-east from Azlal, stands a group of megaeholithic monuments of some interest. They have been visited and described by many travellers, but Watson's account is the most detailed. Round the base of a mound (15 ft. high) of yellow sandstone lies a circle of sixty-seven large stones, one of which (at the side) is more than 20 ft. high. In the vicinity are several other groups, some of which are still larger blocks. Roman roads (see Africa, Roman) seem to have run from Tanger southwards to the neighbourhood of Mequinez (Mînakas), and from Azlal to the south of Rabat; and Roman sites are in several instances marked by considerable remains of masonry. At Kasar Farâ'în (Pharaoh's Castle), on the western slope of J. Zarhôn, are the ruins of Volubilis. The enceinte, constructed of large stones and flanked by round towers, is 12,000 ft. in extent. Four gates are still recognizable, and a triumphal arch erected in A.D. 216 in honour of Caracalla and Julia Domna. The stones of this site have been used for Mequinez Mînakas. Banasa (Colonia Aelia, originally Valencia) is identified with the ruins of Siddi Ali Bû Jenun, and Thamusida with those of Siddi Ali Bû Sâ'îd. At Shamâni, up the river from Larais, the city of Lixus (Triphora), has splendid specimens of Punic and Roman stonework, and the similar remains on the headland of Mûlaî Bû Sâhlmah probably belong to the Mudejara of Polybius. Of early Moorish architecture good examples are comparatively few and badly preserved. Besides those in Fâs, Mînakas, and Marrâkesh, it is sufficient to mention the mausoleum of the Beni-Mardin (13th to 16th centuries) at Shellah, which, with the adjoining mosque, is roofless and ruined, but possesses a number of funeral inscriptions.

The earliest records touching on Morocco are those of Hannibal Periplus, which mentions that Carthaginian colonies were planted along the coast. The savage and inhospitable tribes with whom they came in contact included cave-dwellers; but megaeholithic remains point to a yet earlier race. It is not till the last century B.C. that Moroccan Berbers are found supplying troops to Pompey or Sertorius, and later, under Augustus, becoming themselves incorporated in the Roman province of Mauretania (q.v., and also Africa, Roman). But the Roman province proper only extends to the Bû Ragrîd, on which Sala, now Salli, was its outpost; Volubilis was at first dependent on it, but was made an independent state, and became an independent city. In the fifth century A.D. the country became subject to the Vandals and, about 618, to the Goths.

1 Gentil, in La Géographie, No. 3 (1908), describes the Siroa region, which, N.N.W. of Tikrit, connects the Anti Atlas and the High Atlas. The Siroa volcano compares with the finest volcanoes of Europe.
MOROCCO

The coming of the Arabs under 'Oqba ('Okba) in 682 was of far greater moment, though it was not till twenty years later that his successor, Missa ibn Naskir, undertook a successful expedition as far as Tafslat and the Dra'a. The force of ten thousand Arabs and Egyptians with whom Tarik (Tārik) ibn Zāid held the Tangier district in 710 was trebled by the enrolment of the Berbers, who enabled him next year to invade Spain, burning his boats behind him (see CALIPHATE, § C. Abbasids). But the Moroccan Berbers shewed no better spirit of war, and in 739 successfully revolted, setting up their first independent ruler, Maïsara. Their kinsmen in Spain followed suit with equal success, and though subdued for a time, they retained their independence in certain parts till the 11th century, when, as masters of Granada, they subjugated their implacable foes, the Arabs; and finally, under the Murabit and Mulwabhard dynasties, conquered all Mahommedan Spain.

The recorded history of the Moorish Empire commences with the settlement near the Roman ruins of Volubilis in A.D. 788 of Idris the elder (Idris b. Abdallah), one of the fugitive descendants of Mahomet during the struggles between rival claimants of the caliphate. Isâm had then been dead for eighty years, but Idris and his son, Idris II., the builder of Fez, extended its influence, uniting the Berbers into a kingdom. Their line controlled a limited portion of northern Morocco for nearly two centuries, in part supplanted by the Mūkna in 923, until displaced by the Maghrawā in 988. These two dynasties were exterminated in 1061 by Yusef I. (bin Tashfin), founder of the Murabit dynasty of Berbers (Almoravides), who added the remainder of Morocco, most of Spain and Portugal, and Tlemçen. Their principal existing monument is the city of Marrakesh. In 1119 the Murabit power was overthrown by another religious leader, Abd el Mumin at the head of the Mawâhid—i.e. "unitarian"—-editor (Almohades), under whom the Moorish Empire reached its zenith at the close of the 12th century. It then included, in addition to the Murabit realm, what now are Algeria, Tunisia and Tripoli, extending to the frontier of Egypt, which they were prevented from occupying by the rise of Saladin. Before the middle of the 13th century they had been driven out of Spain, and had lost at last what was known as Morocco, whence, between 1272 and 1280, they were ousted by the Beni Marin (Marrinides). To them we owe the Girâla, Hasan and Kûtûbiya towns of Seville, Rabat and Marrakesh respectively, the Tore de Oro at Seville, Gibraltar Castle, and the towns of Rabat and Al kâșar. It was under their rule that Francs of Assias dispersed to Morocco the first Christian missionaries of modern times. (See ALMORAVIDES and ALMOHADAS.)

The new dynasty differed from the two which had preceded it in being frankly part of a Berber tribe, the Zenata, who carved out a kingdom for themselves. Having assisted the Murabit and Mulwâhidis respectively at the battles of El Arcos (1105) and Las Navas (1221), the defection of their amir on that occasion offered an opportunity for Abd el-Haqq, the son of their general, to attempt the overthrow of the reigning house. At first the Beni Marin professed allegiance to Tunis, where the Hafsîs, a branch of the Mulwâhidis, had thrown off the Moorish yoke and secured acknowledgment in northern Morocco and Spain. But they were soon in a position to proclaim complete independence, and by the time that Abû Bakr, the third son of Abd el-Haqq to succeed him, died, in 1258, they held sway over all that is now known as Morocco, and 1269 saw the death of the last Mulwâhid prince.

On the death of Abû Bakr there succeeded Yâkûb II., one of the few amirs of Morocco who have left a name for just administration and for philanthropic undertakings. Although of strict religious habits, he displayed no bigotry, studying philosophy, and entering into friendly intercourse with Europeans, whom he encouraged to trade with Salli. In 1261, 1275 and 1277--79, he undertook successful expeditions to Spain, and again in 1284, this time, in alliance with Alphonso of Leon, against his rebel son Sancho. But Alphonso dying during the struggle, Yâkûb found himself master of his country, and Sancho had to acknowledge his suzerainty. All Mahommedans within his realm were freed from all taxes, and all the Arabic manuscripts of the country—thirteen loads—were despatched to the college Yâkûb had built in Fez.

But Yâkûb did not live to reap the benefits of his conquest, which were enjoyed by his son, Yusef IV. (1286), who was courted by his father's old foes, entering into amicable relations with Tunis, Egypt, Arabia, and the neighbouring European states. With the contemporaneous Beni Zeïyan dynasty of Tlemçen, sworn foes of his house, however, he was still at war when stabbed (1307) in the new town of Tlemçen, which he had built while conducting a siege of the old town. A second siege was begun in 1335, and Tlemçen fell in 1337 to the fourth ruler of the dynasty, Ali V., Abû 'l Hasan, better known as "The Black Sultan." Unsuccessful in his invasion of Spain and Tunisia, Ali had eventually to abdicate in 1351 in favour of his rebel son, the famous "Abu Ainân," Fâris I., who during a short reign recovered Algeria and Tunisia.

The Beni Marin were soon driven back, till a few years later Tlemçen alone remained to them, and this they held only till 1365, which latter year saw the fall of the dynasty, the parts being divided among rival claimants, and the Portuguese began to obtain footholds on the coast, Ceuta being lost to them in 1415. Al Kasar in 1458, and Azilal and Tangier in 1471.

On the failure of the Beni Marin the amirate was seized by Sa'id III., "El Wâtîsî," head of another branch, founder of the short-lived Waṭîsî dynasty. His reign is memorable above all that in which the "Catholic Princes" expelled his co-religionists from Spain, the last amir of Granada and many others taking refuge in Morocco, where in 1492 they built for themselves Tétouan. His son, Mahomet VIII., surnamed "the Portuguese," because so long a prisoner of that people, had to suffer the loss to Portugal of practically all his Atlantic ports but Salîl-Râbat, and of Peñón de Velez to Spain, which had a few years previously captured Melilla. Although two more reigns carried the dynasty down to 1550, it has barely left its mark upon the country. From the beginning of the new century a rising power had been making itself felt in the south, over which the Waṭîsîs never held sway.

The family of sharifs or "nobles"—that is, descendants of Mahomet—popularly known as the Sa'âdi or Hasani (Hosaini), settled in the Dra'a district, but originally came from Sa'âd, Dyast, 1524--1668.

The Arab Invasion, 682-710.
succession was disputed by three of his sons. In 1658 one of them, Zidan, became supreme and reigned twenty years. To subdue rebellions Zidan who obtained the assistance of English troops from Charles I, and, like his father, employed large numbers of European artists in the various palaces he built or completed. The two sons who succeeded him had both become drunkards from intercourse with these foreigners, but a third, Mahomet XIII., called from prison to reign in 1656, proved himself a wise and beneficent ruler. But his friendship for Europeans displeased the more fanatical among his subjects, and after a futile attempt on the part of a central Moroccan "saint" of great reputation to oust him, and the "Christians" on the coast as well, another family of sharifs was invited from Taflilat in order to undertake the task, and by 1649 they were masters of Fez.

Before tracing the history of the Filali dynasty, which still holds its own, it will be convenient to refer briefly to the relations of Morocco with Europe, which subsisted then (17th century) and for many years afterwards, apart from wars with Spain and Portugal, between the Moors and Europeans. From the early part of the 17th century there are records of Christian mercenaries and others in the Moorish service, while intermittent trading expeditions had already brought the principal European ports of the Mediterranean into touch with Morocco. The settlement of European traders in Moorish ports does not appear to have commenced till later; but it soon became an important factor, for the Moors have always appreciated the advantages of foreign commerce, and thus the way was opened up for diplomatic intercourse and treaty privileges. Even while their rovers were scouring the seas and making slaves of the foreigners captured, foreign merchants were encouraged to trade among them under guarantees and safe-conducts. Thus originated all the rights enjoyed by foreigners in Morocco to-day, as subsequently confirmed by treaties. France was the first to appoint a consul to Morocco, in 1577, Great Britain only doing so a century later. For centuries the Moors of Morocco were the only Muslims who were given the right to trade without being met with the same discriminations as those met with by the Moors of Spain. The European traders were welcomed, and the Moors were as a rule friendly with them. The French, however, endeavored to keep in the field of commerce as far as possible a large part of the trading rights reserved for the Moors.

While, from the European point of view, the pirates of the Barbary coast were a bloodthirsty set of robbers, in no way to be distinguished from the sweepings of Western religious civilization who scoured the seas farther east, from the standpoint of the Moors they were the pious religious warriors for the faith, who had volunteered to punish the Nazarenes for rejecting Mahomet, and it is difficult to realize the honour in which their memory is held save by comparison with that of the Crusaders, in which the positions were exactly reversed. The Moorish rovers approached as nearly to an organized navy as anything the country ever possessed, and at times they were fitted out by the state, to whom their prizes therefore belonged. They made descents on the shore of Europe even as far as Devon and Cornwall, carrying off the population of whole hamlets.

Salli, Ma'mora (Mechediya), Larash, Tangier, Ceuta, Tetuan, and Badas were their principal rendezvous in Morocco, and their vessels, an assortment of almost every known build and rig of the day, varied greatly in numbers and size. It is probable, however, that contemporary writers greatly over-estimated their importance. They appear to have flourished chiefly throughout the 16th, 17th and 18th centuries, and to have attained the zenith of their power during the latter part of the 17th century. A great impetus was given to their raids by the expulsion of the Moors from Spain in 1615, and their operations were facilitated later by the recovery of most of the Moorish ports from foreign hands. The varying influence of the different European states could be gauged at first by the prices they were compelled to pay to ransom their captive subjects, and later by the annual tribute which they were willing to present to protect their vessels. Some countries continued the payment well into the 19th century, although the slavery of Christians in Morocco had been abolished by treaty in 1814.

During the time that piracy flourished hundreds of thousands of foreigners suffered captivity, torture and death in Morocco rather than abjure their faith, the one condition on which a measure of freedom within Morocco was offered to them. The horrors of that time were keenly felt in Christendom, and collections were constantly made at church doors for the ransom of Moorish captives. Frequent expeditions for that purpose were undertaken by members of religious brotherhoods, not a few of whom themselves became martyrs. The lot of the European slave was infinitely worse than that of the negro who indifferently embraced Islam, and was at once admitted to equality in all points save freedom. They were principally employed on public works or in galleys under the task-master's lash, both men and women being subjected to every indignity.

The record of the Filali dynasty may now be considered. The first of this line proclaimed in Fez was Mahomet Fudj Possess, Bokhari,

peace among the more turbulent of his subjects. From early in the century Sâs had practically maintained independence, but in 1891 was reduced to submission, as also were subsequently the other great Berber centres, one by one, till the land had rest. Fighting between the Rifians and Spaniards in 1894 having involved the sultan in the payment of some £650,000 indemnity, he was on his way to recover this from the culprits when he died in camp and was interred at Rabat.

The Reign of Abd-el-'Aziz IV., his son by a Circassian slave who possessed great influence over him. His trusted chamberlain, Si Ahmed ben Mûsa, became Wazir regent, and put down all opposition, ruling with a firm, wise hand till 1900, when he died just as his ward attained his majority. Drastic changes thereon took place, and a new set of ministers came into power. The young sultan now showed himself desirous of acquiring and practising foreign arts and of introducing foreign reforms. Under his mother's advice he sought especially the friendship and advice of Great Britain, on whose disinherited friends he believed he could rely. But lack of training and experience frustrated his praiseworthy efforts, and he became the prey of schemers and speculators, who pandered to his worst traits and squandered his treasure.

This turn of affairs aroused the fanaticism of his people, and in 1902 the Berber tribes of the Algerian frontier rose in rebellion under Jelâli Zarbûni, nicknamed "Bu Hamûra," who claimed to be fighting on behalf of the sultan's brother Mahomet, already imprisoned in Mequinez for revolt. Unable to subdue the rebellion, which did not, however, affect the rest of the empire, Abd-el-'Aziz borrowed money from France to reorganize his army, but failed to effect his purpose. Meanwhile a local shief, Mulai Ahmed er-Raisuli, made himself master of the district round Tangier, holding even foreigners to ransom, and creating a false impression abroad as to the general state of the empire.

The end appeared near when by a declaration, signed in London on the 5th of April 1904, Great Britain, in return for concessions in Egypt, agreed not to interfere with French action in Morocco. In this declaration, one of the series of arrangements marking the determination of the entente cordiale, France declared that she had no intention of changing the political status of Morocco. She designed, however, a system of "pacific penetration," and administrative, economic, financial and military reforms—forms which the Moorish court did not desire. By a separate convention with Spain in October 1904 the interests of that country were safeguarded, and it seemed that the Anglo-French agreement had the approval of all the powers. Some weeks before its conclusion its terms had been communicated to Germany, and four days after its signature Count Bûlow had stated in the Reichstag that there was no ground to apprehend that German interests ("essentially economic") in Morocco would be disregarded. During the remaining months of 1904, however, and in the opening months of 1905, Chancellor Bethmann-Hollweg gave great weight to the increasing influence of France in Europe, but remained quiescent until after the reverses to the Russian arms in Manchuria, when it was judged in Berlin that the time had arrived for Germany to become the arbiter of European policy; and the means to demonstrate her position were found in the Moroccan question. After having turned a deaf ear to the demands of the Pan-Germanic party for the "vindicatoin" of German rights in Morocco, after in fact nearly a year of acquiescence in the predominant position of France in that country² the German government now complained of being ignored in the Anglo-French arrangement and proceeded to extend its patronage to the Sultan of Morocco.

On the 31st of March 1905 the German emperor landed at Tangier and had conferences with the sultan's representatives. The emperor was reported to have declared that he had come to enforce the sovereignty of the sultan, the integrity of Morocco, and the equality of commercial and economic interests. The effect of this intervention was soon apparent. The sultan rejected the scheme of reforms proposed by France, and at the suggestion of Germany issued invitations to the powers to meet his representatives and advise him concerning the reforms needed.

The French foreign minister, M. Delcassé, held that there was no need for a conference, but Prince Bûlow used menacing language and after a period of much stress M. Delcassé resigned (June, 1905), the French government thereupon agreeing to the holding of a conference. So far the German policy had triumphed; the conference met at Algeciras on the 16th of January 1906 and engaged in the delicate task of reconciling French claims for predominance with the German demand of equality. Ujhá, the British envoy, gave firm support to their French colleagues, while Austria proved "a brilliant second" to Germany. With great difficulty a scheme of reforms was elaborated, Germany having previously acknowledged the privileged position of France along the Moroccan-Algerian frontier. The general act embodying the resolutions of the conference was signed on the 7th of April; it was accepted by the sultan on the 18th of June, and the ratifications of the act by the other powers were deposited at the Spanish Foreign Office on the 31st of December 1906. The act provided for a Moorish police force from 2000 to 2500 strong, distributed among the eight open ports of Morocco, to be commanded by Moorish kâds, assisted by French and Spanish inspectors and officers, with a Swiss inspector-general—the arrangement to continue for five years. The act provided also for the institute of a state bank (see supra § Finance). Other provisions dealt with (a) the acquisition of land round the ports by foreigners, and the consequent payment by them of the regulated or tèrtie taxes; (b) the more efficient control of the customs administration, first by an annual assessment of the average values of all imports as a basis for the tariff during the following year, and, secondly, by a strict supervision of the administration itself; and (c) the authority of the state over the public services and public works, tenders for which were to be adjudicated impartially without reference to the nationality of the bidder.

Throughout 1906 the country was in a disturbed condition, and while a Franco-Spanish demonstration at Tangier succeeded in obtaining the removal of Raisûli from the governorship of the town, various outrages occurred (including the murder of a Frenchman in the suburbs of Tangier) for which no satisfaction could be obtained.

At length the murder of Dr. Emile Mauchamp at Marrakesh on 19th of March 1907 determined the French to take prompt action. Ujhá, the British envoy, who had been successively envoy to Africa, was instructed by his government to demand the arrest of the of the French, and the French government demanding to have the same thing, a given demand had been given to their demands. This satisfaction 'Abd-el-'Aziz promised in May, and some progress was made towards carrying out the Algeciras programme, the state bank being organized in July 1907. Meanwhile the weakness of the sultan's rule was illustrated in many quarters; near Tangier by the continued activity of Raisûli, that chieftain securing in June another European captive—Sir Harry Maclean, who after over seven months' detention had to be ransomed by the British government for £20,000.

¹ Mulai Mahomet, eldest son of El Hasan and a generally popular prince, was released from prison by 'Abd-el-'Aziz early in 1908 and placed in command of his army. On the defeat of 'Aziz by Mulai Hafid, Mahomet contemplated seizing the throne. He was, however, imprisoned by Hafid in the palace at Fez, where he was reported to have died, in mysterious circumstances, in June 1909.

² Shown inter alia by the landing of 500 Algerian troops at Tangier (a step taken to secure the release of Ion Perdicaris and his stepson, captives of Raisûli), and of a detachment at Rabat.

³ Kaid Sir Harry Maclean (b. 1858) after serving in the British army became instructor to the Moorish army, which he accompanied in several expeditions. He was also colonel of the sultan's bodyguard. For services rendered to the British government he was made a C.M.G. in 1908 and a K.C.M.G. in 1911. On the occasion of his capture he had gone, as he thought, to receive the submission of Raisûli, and had with him or two or ten attendants only. The sum paid for his ransom was subsequently refunded—as to £15,000 by Raisûli himself and the remainder by Mulai Hafid.
At Casablanca at this time works were in progress, with the sanction of the sultan, for improving the harbour. The works were beyond the ramparts, close to the Moslem cemetery; and the neighbouring tribesmen (the Shawia) were excited by reports that the cemetery had been desecrated. On the 30th of July they attacked the European labourers and killed nine of them (three French, three Spaniards, and three Italians), afterwards entering the town and raiding the Jewish quarter. Refugees fled by boat to Tangier with news of the massacre. The French government decided to occupy Casablanca, and a strong naval and military force was sent thither. Before the arrival of the troops the commander of the cruiser "Galilée" landed a party (Aug. 5) to guard the French consulate. The passage of the detachment was opposed, whereupon the "Galilée," aided by the "Du Chayla" bombarded the town. Casablanca was at the same time entered by the tribesmen, who began a general pillage. On the 7th the French troops arrived and were landed, and further fighting took place. Before order was restored nearly every inhabitant had been killed or wounded or had fled; the dead alone numbered thousands. The European colony was, however, saved. Though masters of the town, the French found the Shawia tribesmen still unfixed, and first and after (Jan. 1908) under General Amadé, the French proceeded to the reduction of the Shawia country. At one time the expeditionary force numbered 15,000 men. By June 1908 the district was quiet and thereafter the strength of the force was gradually reduced. The action of France at Casablanca aroused the fanaticism of the tribes of Tafilet and those dwelling near the Algerian border. In November 1907 the Beni Snassen crossed the frontier and were not reduced to submission until after hard fighting. Another outbreak occurred in April 1908, when a French column in the Guir district, west of Figiug was surprised, and had difficulty in beating back the enemy. In that and a subsequent engagement, which resulted in the dispersal of the foe in May, the French casualties were over 200. French and Moorish commissioners were then appointed to preserve order along the frontier.

While thus engaged on the eastern frontier and on the Atlantic coast of Morocco France had given financial and moral support to 'Abd-el-'Aziz, whose position was threatened by his brother Mulai Hafid. An attack on the town of Marrakesh, on the 16th of August 1907, within a fortnight of the bombardment of Casablanca, the ulema of Marrakesh had declared 'Abd-el-'Aziz deposed and Hafid sultan; and from September onwards the tribes round Casablanca opposing the French were supported by troops sent from Marrakesh. Aziz having been furnished with money by the state bank, he was enabled to reach the seaport of Rabat at the head of his army in September 1907. There he was visited by the French minister and appeared willing to grant all the demands of France in return for help against his brother. A loan was forthcoming but no military assistance save that some of 'Abd-el-'Aziz's troops were taken by a French warship to Mazagan. While desultory fighting between the supporters of the rival brothers was proceeding Hafid was proclaimed sultan at Fez on the 4th of January 1908; Hafid now sought support from France, Germany, and other powers, and moving from Marrakesh passed the French lines in the Shawia country, entered Mequinez in May and Fez in June 1908. At length 'Abd-el-'Aziz made an effort to reassert his authority and with a force numbering 4000 he left Rabat in July for Marrakesh. He reached the neighbourhood of that city on the 2nd of August, having received the adhesion of numerous tribes, including the Shawia. On the 19th he started for the final march on Marrakesh. He appears to have been betrayed, for hardly had his force started when it was assailed on all sides, whereupon the tribesmen deserted in a body and the "regulars" ran away. The day was irretrievably lost and 'Abd-el-'Aziz sought safety in flight. On the 22nd he arrived at Settat in the Shawia country, and within the French lines, with only a handful of followers. For a short time he talked of continuing the struggle, but ended by accepting a pension from his brother Hafid and was assigned a residence in Tangier. That town, the last in Morocco to acknowledge Hafid, did so on the 23rd of August; the change of sultans being accomplished without any disturbance of public order.

Germany was anxious for the immediate recognition of Hafid and caused some perturbation in France by a circular to the powers to that effect dated the 2nd of September; the French government replied by proposals for guarantees that Hafid would respect the Act of Algeciras. This course received general assent and Hafid having given the guarantees demanded he was formally recognized as sultan at the beginning of 1909. His relations with Europe were made easier by the conclusion, in February 1909, of a Franco-German agreement designed to avoid all cause of misunderstanding between those powers in Morocco. Germany put on record that her interests in the sultanate were "only economic," and France agreeing to "safeguard economic equality" Germany undertook not to impede the political interests of France in the country.

The weakness of the central government was exemplified by the inability of Mulai Hafid to control the Riff tribesmen, who in July 1909 killed a number of European labourers in the neighbourhood of the Spanish fortress of Melilla (q.v.). Spain sent an army of 50,000 men to vindicate its authority. After a severe campaign the Rifians were reduced to submission (Nov. 1909). Though powerless in the Rif, Mulai Hafid's army succeeded in defeating Bu Hamara's force and in capturing Al-Hafid (Aug. 1909) that pretender, otherwise known as el Roqi. Bu Hamara and many of his followers were taken to Fez. The tortures inflicted upon them evoked strong protests from the European powers. In 1910 Mulai Hafid obtained a loan, chiefly from France, of £4,000,000; the greater part of the loan went to liquidate claims by Europeans against the maghzen.

NOTE.—The dates given are those in which the various rulers acquired soverignty. Many who had already secured the allegiance of certain provinces some time before, and many retained such allegiance long after the greater portion of the empire had accepted a successful rival. European nations in several instances treated with men who were not at the time actual sovereigns, and in some cases were never such.

Geography.—Budgett Meakin, The Land of the Moors (a general description, London, 1901); Ch. De Foucauld, Reconnaissance au Maroc (text and maps (Paris, 1889); E travels for the most extensive, detailed, and original exploration up to that date undertaken in Morocco, admirably illustrated); J. D. Hooker and John Ball, Morocco and the Great Atlas (London, 1878; the trustworthy record of excellent and well-equipped scientific expedition, valuable chiefly for its botanical information); J. D. Hooker, Travels in the Atlas (London, 1878; the narrative of a restricted excursion from Marrakesh); H. de la Martinière, Journeys in the Kingdom of Fez (London, 1889; chief value archaeological); Rafael Pezzé, Les présidios menores de Africa (Madrid, 1898); Jules Eckermann, Le Maroc moderne (Paris, 1886; includes parts not open to Europeans, visited by the author as an officer in the Moorish army); Capt. E. Bonelli, El Imperio de Marruecos (Madrid, 1882; a valuable but similar work, by a Spanish officer); F. de A. de Urgestau, Viajes por Marruecos (Madrid, 1877; descriptions by a Spaniard born in the country and travelling as a native); G. D. Cowan and R. L. N. Johnston, Moorish Lands Leaves (London, 1883; trustworthy despatches with some central Morocco) of Emilien Renou, Description géographique de l'empire du Maroc (Paris, 1846; a compendium of information available at that date); J. Canal, Géographie générale du Maroc (Paris, 1902); Mission de Segonzac, Voyages au Maroc 1899-1900 (Paris, 1903) and later publications of the Segonzac Mission; Ch. Tisot, Recherches sur la géographie comparée de la Mauritanie et Tiziagene (Paris, 1877; a valuable archaeological survey); M. Besnier, "Géographie ancienne du Maroc" and "Revue des descriptions antiques," both in No. III. of Archives marocaines (Paris, 1864); Leo Africanus, Description of Africa, 1526, trans. Pory, 1600; ed. Dr Robert Brown, for Hakluyt Society (3 vols., London, 1896; a wonderful work for its period, always of interest, but the source of many oft-repeated errors in books on Morocco.)

Ethnology.—Budgett Meakin, The Moors (London, 1902; a minute account of manners and customs); James G. Jackson, An Account of the Empire of Morocco (London, 1869; the authoritative description for a century); Georg Hoth, Erscheinungen om Morokos og Fei (a work still of great value; Copenhagen, 1779); Thomas Fellow, Captivity and Adventures, 1730 (ed. Dr. Robert Brown, London, 1890; one of the best and most intimate narratives of the African slave trade); Count Sternburg, The Berarians of Morocco (London, 1898).

Language.—Rev: José Lurchardi, Rudimentos del árabe... de marroccos (Tangier, 1891) and Vocabulario español arábigo (Tangier, 1892); Eng. trans. of the former work by Carew (London, 1900; most useful, but dealing chiefly with the corrupt colloquial speech of the Tangier-Tetuan district); Budgett Meakin, An Introduction to the Arabic of Morocco (Tanger, 1900; vocabulary; grammar, notes, etc., for pocket use, in Roman characters); M. C. W. Baldwin, Morocco-Arabic Dialogues (Tangier, 1892; uniform with the last-named, but in Arabic characters).

Maps.—The most trustworthy general maps are R. de Flotte de Roquevaire, Carte du Maroc (scale 1:110,000; 4 sheets, ed. 1908); the French War Office maps (scale 1:50,000, begun 1906, scale 1:100,000, begun 1909); and the British War Office map (scale 1:110,000, begun 1904). There are numerous district maps. The Dyé Mission published fifteen. (B. M.; K. A. M.)

MORÓN DE LA FRONTERA, or Morón (anc. Arumi), a town of southern Spain, in the province of Seville; 32 m. S.E. of the city of Seville. Pop. (1900) 14,100. It contains an important market, and is a bridle town, and blocks near the right bank of the Guadalquivir. It is connected by rail with Utrera and the Cadiz & Seville line. On the highest elevation to the eastward are the ruins of the ancient castle, of considerable importance during the Moorish period, when Morón, as its full name implies, was a frontier fortress; the castle was afterwards used as a palace by the counts of Urrea. In 1810-1811 it was fortified by the French, but blown up by them in the following year. The chief public building of Morón is the large parish church, which dates from the 16th century. Morón is also famous throughout Spain for its marble and its chalk (cal de Morón), from which the whitewash extensively used in the Peninsula is derived.

Morone, Giovanni (1509-1580), Italian cardinal, was born on the 23rd of January 1509 at Milan, where his father, Count Ieronimo Morone (d. 1525), was grand chancellor. His father, who had been imprisoned for opposing encroachments on the liberties of Milan by Charles V. (whom he afterwards cordially supported), removed to Modena, where his youngest son had most of his early education. Promising to Padua he studied jurisprudence under the celebrated teacher, and afterwards, on the recommendation of Cardinal Moroni, was nominated in 1527 by Clement VIII. to the see of Modena, and consecrated in 1533 after a contest. From 1535 he was constantly entrusted by Paul III. with diplomatic missions; he was nuncio (1536) to Ferdinand, king of the Romans, and legate to the diet of Spire (1542) having successfully resisted the transfer of the diet to Hagenaun on account of the plague (1540). On the 31st of May 1542 he was created cardinal, and was further nominated protector of England, Hungary, Austria, of several religious orders, and of the santa casa at Loreto. With the cardinals Paul Parvis and Reginald Pole he was deputed to open the Council of Trent (Nov. 1, 1542), the place of meeting having been a concession to his diplomacy. The legates arrived on the 22nd of November, but no council assembled. The death of Paul III. (1540) deprived him of a good friend. The views of the Reformers had spread in his diocese, and he was suspected of temporizing with them. He resigned his see (1535) in favour of the Dominican Egidio Foscherari, resigning to himself an annual pension and the patronage of Bergamo. John II. of Castile gave the instanct of the duke of Milan, gave him (1522) the rich see of Novara (which he resigned in 1526 for the see of Albano) and sent him as nuncio to the diet of Augsburg (1555), from which he was immediately recalled by the death of Julius (March 23). In June 1557 Paul IV. imprisoned him in the castle of St. Angelo (with others, including Pole, and Foscherari), on suspicion of Lutheran heresy. The prosecution entirely failed, and Morone might have had his liberty, but refused to leave prison unless Paul IV. publicly acknowledged his innocence. He remained incarcerated till the pope's death (Aug. 18, 1559), and took part in the election of Pius IV. Cenotaph, in the twenty-eighth of his Dialogi XXX. 1563 has a colony on the treatment of heretics, between Pius IV. and Morone, in which the latter maintains: "Errantes in via merencandi, non occidenti." This really hits the position of Morone, a sincere Catholic, to whom persecution was abhorrent. He presided at the Tridentine Council from the 10th of April to the 4th of December 1563, and endeavoured to exercise a conciliatory influence. At the end of 1564 Foscherari died, and Morone was reinstated in the see of Modena. On the death of Pius IV. (1556) he came near to being elected pope. His last days were easy; he died at Rome on the 1st of December 1580, and was buried at S. Maria sopra Minerva. His writings comprise a few letters and orations. His career is that of a good man, struggling for the welfare of his Church against corruptions not essential to the system to which he was devoted.

Moroni (1885); M. Young, Life and Times of Antonio Palaeiro (1860); C. Benavith in Hauck's Realencyclopaedie (1903). (A. G. *)

Moroni, Giambattista (c. 1410-1578), Italian portrait-painter of the Venetian school, was born at Albino near Bergamo about 1512 (or perhaps a few years later), and became a pupil of Bonvicino named Il Moretto. Beyond the record of his works very few particulars regarding him have reached us. Titian, under whom also Moroni, while still very young, is said to have studied (but this appears hardly probable), had at any rate a high opinion of his powers; he said that Moroni made his portraits "living" or "actual" (veri). In truthful and animated portraits Moroni ranks next to Titian himself. His portraits do not indeed attain to a majestic monumental character; but they are full of straightforward life and individuality, with genuine unforced choice of attitude, and excellent texture and arrangement of draperies. There is a certain tendency to a violet-tint in the flesh, and the drawing and action of the hands are not first-rate. The earliest inscribed date discovered for any of his works is 1533. As leading samples may be mentioned,—in the Uffizi Gallery, Florence the "Noblemam pointing to a Flame," inscribed "Et quid zolo nisi ut ardet?"; in the National Gallery, London, the portraits of a Tailor; a member of the Venetian family, Canon Ludovico de Terzi, and others; in the Berlin Gallery, portraits and in Stafford House, the seated half-figure of the Jesuit Ercole Tato. The signature is termed "Titian's Schoolmaster"—not as indicating any real connexion between the sitter and Titian, but only the consummate excellence of his work. Besides his portraits, Moroni painted, from youth to his latest days, the ordinary round of sacred compositions; but in these he falls below his master Il Moretto. One of the best is the "Coronation of the Virgin," in S. Alessandro della Croce, Bergamo; also in the cathedral of Verona, "SS Peter and Paul," and in the Bresa of Milan, the "Assumption of the Virgin." Moroni was engaged upon a "Last Judgment," in the church of Corlago, when he died on the 4th of February 1578. (W. M. R.)

Morosini, a noble Venetian family, probably of Hungarian extraction, which gave many doges, statesmen, generals and admirals to the Venetian Republic, and Cardinals to the Church. It first became prominent at the time of the emperor Otto II. owing to its rivalry with the Calipri family, whom it succeeded in subjugating by the end of the 10th century. Domenico Morosini (d. 1136), elected doge in 1148, waged war with success against the Istrian towns and Istrian towns from them. Marino Morosini (d. 1252) was elected doge in 1249; Michele was doge from June 1382, until his death in October of the same year.

Andrea Morosini (1558-1618) was a famous historian and was entrusted by the Venetian senate with the task of continuing Paolo Paruta's Annales Veneti, in Latin. His history of Venice was published by his brother in 1623 (Venice), and translated into
MORPETH—MORPHEUS

Italian by Senator Girolamo Molin (Venice, 1782). Among his other works are: Le Imprese ed espedizioni di terra santa, &c. (Venice, 1627); De ista vasa repentina ad Istriae orae gestis, &c. (in the Corner-Duodo collection of MSS.; De forma repentina venae in MS. in the Bibliothèque Nationale in Paris. His life has been written by Luigi Lollini (1623), by Niccolo Crasso (1621), and by Antonio Pulazzoli (1620).

Francesco Morosini (1618–1694) was one of the greatest captains of his time. As a young man he fought against the Turks and the pirates, and after signally distinguishing himself at the battle of Naxos in 1650 he was appointed commander-in-chief of the Venetian navy. He then conducted a series of successful campaigns against the Turks, but was recalled in consequence of the intrigues of his rival the Provveditore Antonio Barbaro (1661). But when Candia was attacked by a large force, under the terrible vizir Kephripil, Morosini was sent to relieve the fortress in 1667; the siege lasted eighteen months, but Morosini, in spite of his prodigies of valour, was forced to surrender to save the surviving inhabitants. He was tried, but acquitted of all blame, and on the renewal of the war with the Turkish Empire in 1684 he was again appointed commander-in-chief, and after several brilliant victories he reconquered the Peloponnesus and Athens; on his return to Venice he was hailed with enthusiasm, and given the title of ‘Peloponnesius.’ In 1688 he was elected doge, and in 1693 he took command of the Venetian forces against the Turks for the fourth time; the enemy which had been cruising in the archipelago withdrew at his approach, so great was the terror inspired by his name. While wintering at Napoli di Romani (Nauplia) he died on the 6th of January 1694.

MORPETH, a market town and municipal and parliamentary borough of Northumberland, England, situated in a hilly valley on the Wansbeck, 17½ m. N. of Newcastle by the North Eastern railway the junction of several branches with the main line. Pop. (1901), 6138. The Wansbeck winds round the town on the west, south and east, and a rivulet, the Cottingburn, bounds it on the north. The parish church of St. Mary, a spacious building of the 13th century, is situated on Kirk Hill, a short distance from the town. It has a good example of a Jesse window. Nothing remains of the old castle except the gateway. The valley of the Wansbeck above Morpeth is well wooded and very picturesque. By its side are fragments of Newminster Abbey, a wealthy foundation of the 12th century, occupied by monks from Fountains in Yorkshire; and Mitford, with its Norman and Early English church, and ruins of a Norman castle and a manor-house of the 17th century. To the north of Morpeth a good specimen of the peel tower of the 15th century is seen at Cockley Park. Industries of Morpeth include tanning, brewing, milling, iron and brass founding, and the manufacture of flannels, agricultural implements, and bricks and tiles. The parliamentary borough, within the Wansbeck division of the county, returns one member and extends 8 m. eastward to the coast, including the town of Blyth. Morpeth is governed by a mayor, 4 aldermen and 12 councillors. Area, 326 acres.

The manor of Morpeth is said to have been granted to William de Merlay soon after the Conquest and passed with the borough from his family to those of Graystoke, Dacre and Howard, earls of Carlisle, with whom it remains. The town is a borough by prescription and grew up round the castle attributable to the above William de Merlay the younger granted the burgesses right to hold of him and his heirs “as freely as the charter of the king purporting which he held of the king by gift.” Charles II, incorporated the town in 1662 under the government of two bailiffs who were chosen every year in the following manner: the bailiffs for the time being chose two jurors from whom the commonly elected four burgesses, and from these four the steward of the lord of the manor being chosen for one year. This was continued until the Municipal Reform Act of 1835. In 1800 a market on Wednesday and a fair on the Feast of St Mary Magdalene were granted to Roger de Merlay, and in 1852 the fair was extended for two days. The market rights still belong to the lord of the manor.

MORPHEUS, in Roman mythology, one of the sons of Somnus, the god of sleep. He was a personification, apparently invented by Ovid (Metam. xi. 635), of the power that calls up human shapes (morphai) of all kinds to the dreamer. His brothers Phobetor and Phantasus assumed the forms of all kinds of animals and inanimate things.

MORPHINE, the chief alkaloid of opium (g.), to which the medicinal action of the former is mainly due. It is not used itself in medicine owing to its insulubility in water and ether. The preparations of morphine are incompatible with salts of iron, copper and mercury, also with lime water and alkaline earths and substances containing tannin. With ferric chloride it forms a deep red colour.

The preparations of morphine in the British Pharmacopoeia are as follows: From Morphinae Hydrochloridum are made five sub-preparations: (1) Liquor Morphinae Hydrochloridum, strength 1% or about 43 g. of the hydrochloride to the fl. oz.; (2) Suppositoria Morphinae, made with a basis of oil of theobroma, strength 1 gr. per suppository; (3) Tinctura Morphinae et Morphi; (4) Tropiscus Morphinae, strength 1 gr. in each; (5) Tropiscus Morphi et Ipecacuanhae, strength 1 gr. of morphine hydrochloride and 1 gr. ipecacuanha in each. From Morphinae Asetas, a white soluble amorphous powder, is made Liquor Morphinae Asetatis, strength 1% or 44 g. of the acetate to 1 fl. oz. From Morphinae Tartras, a white crystalline powder, are prepared, Injeclio Morphinae Hypodermica, containing 5% of morphine tarsate, and Liquor Morphinae Tartras. Morphinae Sulphatis is not official in the British Pharmacopoeia but is official in the United States, the U.S.P. Tropiscus Morphi et Ipecacuanhae and Pulvis Morphinae Compositus (Tull’s powder) being made from it. Hypodermic tabloids of morphine sulphate either alone or combined with atropine are much in use. Various non-official preparations of morphine are in use, such as dionin, heroin, glycophorm and peronin.

Therapeutics.—Morphine is an analgesic and hypnotic, relieving pain and producing deep sleep. As contrasted with opium it differs in being less astringent and constipating. Morphine is the greatest anodyne we possess, and no drug yet discovered equals it in pain-relieving power. The most frequent mode of administration is hypodermic injection, on account of the extreme rapidity with which it is absorbed. In cases due to violent sciatica relief and even permanent cure has been obtained by the injection of morphine directly into the muscles of the affected part, and in the treatment of renal and hepatic colic morphine given subcutaneously will relieve the acute pain consequent on the passage of biliary and urinary calculi. A violent paroxysm of asthma may be arrested by the administration of morphine subcutaneously, but the practice should not be continued, as there is great danger in a chronic disease that the patient may become the victim of morphinism. Morphine is recognized as one of the most useful drugs in the treatment of éclampsia, early injection often arresting the fits. In the cough of phthisis minute doses are of service, but in this particular disease morphine is frequently better replaced by codeine or by heroin, which checks irritable coughs without the narcotism following upon the administration of morphine. In bronchitis with profuse expectoration the use of morphine is particularly dangerous, as it is likely to check the cough so necessary for getting rid of the secretion, but in the converse condition it usefully allays the harassing cough by diminishing the excitability of the respiratory centre. In the treatment of advanced pulmonary disease the heart morphine relieves the distress and restlessness that the patient suffers. It should however be withheld if the heart has undergone fatty degeneration. Morphine is a sheet anchor in the later stages of cancer and other painful diseases, rendering the life of the patient one of comparative comfort. If given in excess the drug is eliminated by way of the intestines and kidneys. It
MORPHOLOGY

863

is also excreted in the milk; hence the danger in the administration of large doses of morphine to nursing mothers.

Morphine-scopolamine anaesthesia was introduced in 1902 by Steinbückel. It has been used by some surgeons for the production of anaesthesia previous to the administration of ether or chloroform, but the use of the method is now more usually relegated to obstetric practice.

Morphinism (Morphinomania).— Chronic morphine poisoning is very common, as morphine taken constantly creates a habit. Once acquired the habitual depends on the drug for a comfortable existence, and as the poison becomes slightly tolerant of the drug, the original dose no longer suffices. The total amount of morphine indulged in by the habitual morphinist may reach an astonishing figure; 15 grs. a day is said to be common, and some medical writers record cases in which 25 grs. were administered to one patient in 24 hours.

The early stages of morphinism are marked by moral degeneration; the patient seems to lose all sense of right and wrong, and will lie most plausibly and even thieve to obtain the drug; personal disorderliness, disregard of time, neglect of business and decline of family affection become soon evident. Physical symptoms also appear; the face assumes an earthy colour, the body wastes, constipation is usually present to an extreme degree, the secretions become arrested, loss of appetite and indigestion follow and the mouth is parched. The nails become brittle and the skin dry, sterility shows itself in women and sexual impotence in men. While not directly causing death, morphinism so lowers the bodily powers that the patient is easily carried off by any form of exposure.

The withdrawal of morphine from a morphine habit is followed by a train of alarming symptoms. As the time approaches for the usual dose there is marked restlessness, followed by excitement and later by chills, pallor, sinking, nausea, vomiting, delirium tremens, and coma. Horrible mental depression and melancholia are present, and there may be hallucinations of vision and hearing passing into violent delirium. At this stage collapse may set in, the patient becomes faint, the limbs twitch, the heart beats fast, and incontinence of urine and faeces becomes common. The condition may even go on to a fatal result should morphine be continuously withheld; but injection of even a small quantity of morphine causes those symptoms to cease abruptly. The sudden withdrawal of morphine should therefore be prevented by substituting other narcotics for large quantities of the drug, but gradually diminishing doses given by the physician should be substituted. For the successful treatment of morphinism, continuous observation of the patient is necessary, in place where he is supervised so that he can obtain no morphine. Isolation in a hospital is the best, as friends may give way to entreaties and servants be bribed. The " tapering off of the dose is the best method. After some time the strict supervision lasting over a long period, usually a year, are necessary to prevent relapse. The lowered bodily health requires to be built up, and a long sea voyage under adequate supervision is usually recommended.

MORPHOLOGY, (Gr. morphē, form), a term introduced by Goethe to denote in biology the study of the unity of type in organic form (for which the Linnaean term Metamorphosis had formerly been employed). It now covers the entire science of organic form. There are numerous restricted senses of the term, the most obvious, and which we shall deal with it as a substantive side of zoology and botany. 

Historical Outline.— If we disregard such vague likenesses as those expressed in the popular classifications of plants by size into herbs, shrubs and trees, or of terrestrial animals by habit into beasts and creeping things, the history of morphology begins with Aristotle. Founder of comparative anatomy and taxonomy, he established eight great divisions (to which are appended certain minor groups)—Viviparous Quadrupeds, Birds, Oviparous Quadrupeds and Apida, Fishes, Malacia, Malo-straica, Entoma, and Ostracodermata—distinguishing the first four groups as Enaïma ("with blood") from the remaining four as Anaima ("bloodless"). In these two divisions we recognize the Vertebra and Invertebra of J. B. P. A. Lamarck, the first four groups corresponding with the Mammals, Birds, Reptiles, Fishes, whilst the others agree more loosely with the Cephalopods, Fishes, and Invertebrates other than the Cephalopods. Far from committing the mistake attributed to him of reckoning Bats as Birds, or Cetaceans as Fishes, he discerned the true affinities of both, and erected the latter into a special γένος beside the Viviparous Quadrupeds, more not only on account of their absence of limbs than of their aquatic habit. Not only is his method inductive, and his groups founded on the aggregate of known characters, but he foreshadows such generalizations as those of the correlation of organs, and of the progress of development from a general to a special form afterwards established by G. L. Cuvier and K. E. von Baer respectively.

In the correspondence he suggests between the scales of Fishes and the feathers of Birds, or in that hinted at between the fins of Fishes and the limbs of Quadrupeds, the idea of homology is nascent; and from the compilation of his disciple Nicolaus of Damascus, who regards leaves as imperfectly developed fruits, he seems almost to have anticipated the idea of the metamorphosis of plants. Even after the reappearance of Aristotle's works in the 13th century, little can be recorded but revivals of his conclusions. Monographs on groups of plants and animals frequently appeared, those of P. Belon on Birds and G. Rondelet on Fishes being among the earliest; and in the former of these (1555) we find a comparison of the skeletons of Bird and Man in the same posture and as nearly as possible bone for bone—an idea which, despite the contemporaneous renaissance of human anatomy initiated by Vesalius, disappeared for centuries, unappreciated save by the surgeons Ambrosio Paré, B. Palissy, like Leonardo da Vinci before him, discerned the true nature of fossils; and such flashes of insight continued to appear from time to time during the 17th century. Thus, Joachim Jung recognized the "distinction between root and stem, the difference between leaves and foliaceous branches, the transition from the ordinary leaves to the folia floris," and W. Harvey anticipated the generalizations of modern embryology by his researches on development and his theory of epigenesis.

The encyclopaedic period of which Gesner is the highest representative was continued by Aldrovandi and others in the 17th century; but, aided by the Baconian movement, then influencing all scientific minds, it developed into one of genuinely systematic aim. At this stage of progress the most important part was taken by John Ray, whose classificatory labours among plants and animals were crowned with success. He first expelled the fabulous monsters and prodigies of which the encyclopedists had handed on the tradition from medieval times, and succeeded, particularly among plants, in distinguishing many natural groups, for which his own terms sometimes survive—e.g. Dicotyledons and Monocotyledons, Umbelliferae and Leguminosae. The true precursor of Linnaeus, he introduced the idea of species in natural history, and reformed the practice of definition and terminology. Of the works which followed up Ray's systematic labours, none can be even named until we come to those of his great successor Linnaeus, whose grasp of logical method and lucidity of thought and expression enabled him to reform and reorganize the whole labours of his predecessors into a compact and definite "systema naturae." The very genius of order, he established a new term taxonomy, not only by the introduction of the binomial nomenclature and the renunciation of descriptive terminology and method, but by the subordination of the species under the successive higher categories of genus, order and class, so reconciling the analytic and synthetic tendencies of his predecessors. Although the classification of plants by the number of their essential organs is highly artificial, it must be remembered that this artificiality is after all only a question of degree, and that he not only distinctly recognized its provisional character but collected and extended those fragments of the natural system with which A. de Jussieu soon afterwards began to build. His classification of animals, too, was largely natural, and, though on the whole he lent his authority to maintain the notion of three kingdoms of nature, he at least at one time discerned the fundamental unity of animals and vegetables, and united them in opposition to the non-living world as Organisata. At the same time, it is clear that he was still far more a scholastic naturalist than a modern investigator.

While the artificial system was at the zenith of its usefulness, Bernard de Jussieu was arranging his gardens on the lines afforded by the fragmentary natural system of Linnaeus. His ideas were elaborated by his nephew Antoine de Jussieu, who published diagnoses of the natural orders, so giving the system its modern character. Its subsequent elaboration and definite establishment are due mainly to the labours of Pyrame de
MORPHOLOGY

Candolle and Robert Brown. The former concentrated his own long life and that of his son upon a new “systema naturae,” the colossal *Prodromus systematis naturalis* (20 vols., 1818-1827), in which 80,000 species were described and arranged. Meanwhile the penetrating genius of Brown enabled him to unravel such structural complexities as those of Conifers and Cycads, Orchids and Proteaceae, thus demonstrating the possibility of ascertaining the systematic position of even the most highly modified floral types. Both Candolle and Brown were thus no mere systematists, but genuine morphologists of the modern school.

The labours of Bernard and Antoine de Jussieu initiated a parallel advance in zoology, the joint memoir on the classification of mammals with which Cuvier and Geoffroy St-Hilaire almost began their career receiving its dominant impulse from the “genera” of Antoine. Cuvier’s works correspond in zoology to those of the whole period from the Jussieus to Brown, and epitomize the results of that line of advance. Although, in some respects preceded by A. von Haller and J. Hunter, who compared, though mainly with physiological aim, the same parts in different organisms, and much more distinctly by Vicq d’Azur, the only real comparative anatomist of the 18th century, he opens the era of detailed anatomical research united with exact comparison and clear generalization. The *Regne animal* (1817) and the theory of types (vertebrate, mollusc, articulated, and radiate) are the results of this analytical and synthetic mark the reconstitution of taxonomy on a new basis, henceforth to be no longer a matter of superficial description and nomenclature but a complete expression of structural similarities and differences. In Germany, L. H. Bojanus, J. F. Meckel, C. T. von Siebold and Johannes Muller, with his many pupils, carried on the work; in France, too, a succession of brilliant anatomists, such as A. de Quatrefages, A. Milne-Edwards and H. de Lacaze-Duthiers, were his intellectual heirs; and in England he has been admirably represented by Sir R. Owen.

It is now necessary to return to Linnaeus, whose more speculative writings contain, though encumbered by fantastic hypotheses, the idea of floral metamorphosis. About the same time, and quite independently, C. F. Wolff, the embryologist, stated the same theory with greater clearness, for the first time distinctly reducing the plant to an axis bearing appendages—the vegetative leaves—which become metamorphosed into bud-scales or floral parts through diminution of vegetative force. Thirty years later (1818) a work was also published by Goethe in his now well-known pamphlet (*Versuch der Metamorphose der Pflanzen erklâren*, Gotha, 1790). In this brilliant essay the doctrine of the fundamental unity of floral and foliar parts is clearly enunciated, and supported by arguments from anatomy, development and teratology. All the organs of a plant are thus modifications of one fundamental organ—the leaf—and all plants are in like manner to be viewed as modifications of a common type—the *Urflanze*. Whether, as some historians hold, his “Urflanze” was a mere ideal archetype, bringing forth as its fruit the innumerable metaphysical abstractions of the Naturphilosophie, and leading his countrymen into all the extravagances of that system; or whether, as E. H. Haeckel maintains, it represented a concrete ancestral form, so anticipating the view of modern evolutionists, it is certain that to him F. W. S. von Schelling was indebted for the foundation upon which he erected his philosophic edifice, as also that Goethe shared the same ideas. It must be remembered that he lived and made progress for forty years after the publication of this essay, that he was familiar with the whole scientific movement; that he was the result of his visionary views of Lamarck and Geoffroy St-Hilaire; it is not therefore to be wondered at that his writings should furnish evidence in favour of each and every interpretation of them. His other morphological labours must not be forgotten. Independently of Vicq d’Azur, he discovered the human premaxillary bone; independently of L. Oken, he proposed the vertebral theory of the skull; and before S. C. Savigny, he discerned that the jaws of insects were the limbs of the head.

In 1813 A. P. de Candolle published his *Théorie élémentaire de la botanique*, which he developed into the classic *Organographie végétale* (1827). He established his theory of symmetry, reducing all flowers to “symmetrical” groupings of appendages on an axis and accounting for their various forms by cohesion and adhesion, by arrested or excessive development. The next advance was the investigation by W. P. Schimper and A. Braun of *phytolaxis*—the ascending spiral arrangement of foliar and floral organs—thus further demonstrating their essential unity.

The term morphology was first introduced by Goethe in 1817; in a subsequent essay (Zur Naturwissenschaft überhaupt, besonders zur Morphologie). It did not come into use in botany until its popularization by Auguste de St-Hilaire in his *Morphologie végétale* (1841), and in zoology until later, although De Blainville, who also first employed the term *type*, had treated the external forms of animals under “morphologic.” Though the Naturphilosophie of Schelling and its countless modifications by his followers, its mystical theories of “polarization” and the like, its apparatus of assumption and abstraction, hypothesis and metaphor, cannot here be discussed, its undoubted services must not be forgotten, since it stimulated innumerable reflective minds to the earnest study of natural science, gave a powerful impulse to the study of comparative anatomy and vindicated the claims of philosophic synthesis over those of analytic empiricism. As a result of the many and manifold analyses and synthesis, many authors, including Schimper (1841), have adherents, which led to the doctrine of the morphological type; others metaphysical, others mystical or poetic, others, again, more especially scientific; but its most typical and picturesque figure is Lorenz Oken, who epitomizes alike the best and the worst features of the school, and among whose innumerable pseudo-morphological dreams there occasionally occurred suggestions of the greatest fruitfulness—notably, for instance, the independent statement of the vertebral theory of the skull.

By far the most distinguished anatomist of the transcendental school is Geoffroy St-Hilaire, who, being comparatively free from the extravagances of Oken, and uniting a depth of morphological insight scarcely inferior to that of Goethe with greater knowledge of facts and far wider influence and reputation in the scientific world, had greater influence on the progress of science than either. He started from the same studies of anatomical detail as Cuvier, but, influenced by Buffon’s view of unity of plan and by the evolutionary doctrines of Lamarck, diverging into new lines, and again reached that idea of serial analogies which we have so frequently noted the independent origin. His greatest work, the *Philoaneomy (1818)*, contains his principal doctrines. These are: (1) the theory of unity of organic composition, identical in spirit with that of Goethe; (2) the theory of analogues, according to which the same parts, differing only in form and in degree of development, should occur in all animals; (3) the “prinzip des connexions,” by which similar parts occur everywhere in similar relative positions; and (4) the “prinzip du balancement des organes,” upon which he founded the study of teratology, and according to which the high development of one organ is allied to diminution of another. The advance in morphological theory is here obvious; unfortunately, however, in eager pursuit of often deceptive homologies, he wandered into the transcendentalism of the Naturphilosophie, and seems utterly to have failed to appreciate either the type theory of Cuvier or the discoveries of Von Baer. He defended Buffon’s and Bonnet’s earlier view of unity of plan in nature; and the controversy reached its climax in 1830, when he maintained the unity of structure in Cephalopods and Vertebrates against Cuvier before the Académie des Sciences; at the point of fact, his case was of course utterly defeated; the type theory was thenceforward fully accepted and the Naturphilosophie received its death-blow. Such was the popular view; only a few, like the aged Goethe, whose last literary effort was a masterly critique of the controversy, discerned that the very reverse interpretation was the deeper and essential one, that a veritable “scientific revolution” was in progress, and that the supremacy of morphological and synthetic over descriptive and analytic studies was
The irreconcilable feud between the two leaders really involved a reconciliation for their followers; theories of homological anatomy had thenceforward assured, and the union of the solid matter and rigorous method of Cuvier with the generalizing spirit and philosophic aims of Geoffroy is well illustrated in the works of Owen.

The further evolution of the idea of homology is sketched below, while the extent and rapidity of the subsequent progress of the knowledge of the all the structural aspects of animals and plants alike make a historical survey impossible up to the appearance of the Origin of Species (1859). The needful solution was effected by Darwin. The "Urpfanze" of Goethe, the types of Cuvier, and the like, at once became intelligible as schematic representations of ancestral organisms, which in various and variable segments, have undergone differentiation into the vast multitude of existing forms. All the enigmas of structure become resolved; "representative" and "aberrant," "progressive" and "degraded," "synthetic" and "isolated," "persistent" and "prophetic" types no longer baffle comprehension; conformity to type represented by differentiated or rudimentary organs in one organism is no longer contradicted by their entire disappearance in its near allies, while systematic and morphological become related simply as specialist and generalizer, all through this escape from the Linnaean dogma of the fixity of species. The phenomena of individual development receive interpretation in terms of ancestral history; and embryology thus becomes divided into ontogeny and phylogeny—the latter, too, coming into intimate relation with palaeontology—while classification seeks henceforth the reconstruction of the genealogical tree.

All these results were clearly developed in Haeckel's Generelle Morphologie (1866), while the valuable contemporaneous Principles of Biology of Herbert Spencer also gave special attention to the relation of morphology to physiology.

Individuality—Probably no subject in the whole range of biology has been more extensively discussed than that of the nature of organic individuality. The history of the controversy is of interest, since besides leading up to solid results it serves, perhaps better than any other case, to illustrate the slow emergence of the natural sciences from the influence of scholastic thought. Starting from the obvious unity and indivisibility of Man and other higher animals, and adopting some definition such as that of C. F. B. Mirbel, "Tout être organisé, complet dans ses parties, distinct et séparé des autres être organisés," it was attempted with the utmost labor to discover the same conception elsewhere in nature, or rather to impose it upon all others, plants and animals alike. The results of different inquirers were of course utterly disparate. It seemed easy and natural to the morphologist to subdivide the animal, yet difficulties at once arose. Many apparently distinct plants may arise from a common root, or a single plant may be decomposed into branches, twigs, shoots, buds or even leaves, all of which are capable of giving rise independently to new plants; they are not, however, indistinguishable. Haeckel remarks, scarcely any part of the plant can be named which has not been taken by some one for the individual. It is necessary, therefore, briefly to notice some of the principal works on the subject, and these may conveniently be taken in descending order.

While H. Cassini practically agreed with Mirbel in attempting to regard separate plants as individuals, the widest interpretation of the term was that of A. de Candolle and Edward Forbes, who regarded each organ—the bud, leaf, leafy axis, plant organ—as a distinct individual, while the whole of the plant was considered only as a single individual. In this view, there is only a single individual in British, generally discontinuous.

At once the oldest and most frequently maintained view is that while the plant is the entire product of a single seed, alike whether developed into a single plant or extended continuously like a banyan, or multiplied asexually by natural or artificial means like the vegetable shoot, the bud, leaf, leafy axis, plant organ, or any of its appendages as the plant-individual, of which the tree represents a colony, like a branched hydroid polyp. This conception, often attributed to Aristotle, but apparently without foundation, appears disguised in the writings of Hippocrates and Theophrastus—the latter saying, "The bud grows on the tree like a plant in the ground." The aphorism of Linnaeus, "Gemmae totidem herbae," is well known; and in this view C. F. Wolff and Humboldt concurred, while Erasmus Darwin supported it by an appeal to the facts of anatomy and development. The most influential advocate of the bud theory during the first half of the 19th century was, however, Du Petit-Thouars, who, although starting much as usual with a "principle unique d'existence," supported his theory on extensive though largely hypothetical grounds. The first to notice the existence for him the tree is a colony of phytoms, each being a bud with its axillary leaf and fraction of the stem and root. Passing over numerous minor authors, we come to the central work of Alex. Braun (1832), in which the term, the idea of an organism as a colony, of Naturphilosophie with inductive morphology reaches its extreme. He reviews, however, all preceding theories, admits the difficulty of fixing upon any as final, since the plant, physiologically considered, is not a root, shoot, or bud, but is the result of a process as a compromise, or indeed as a partial cutting of the kinship, the adoption of the shoot, as the morphological individual, comparable to an animal, especially the bud, leaf, &c., it includes all the representative characters of the species. Darwin and Spencer on the whole also accept the bud or shoot as at any rate the most definite individual.

The theory of metamorphosis naturally led Goethe, Oken and others to regard the leaf as an individual, while Johannes Müller, J. S. Steenstrup and others adopted the same view on various physiological grounds. C. Gaudichaud elaborated a theory intermediate between this view and that of Du Petit-Thouars, according to which the plant is both an individual, each consisting of a leaf with its subjacent internode of stem, which was regarded as the leaf-base, and this was supported by Edward Forbes and others, while the nominally converse view—that of the leaf as a membranous expansion of the stem-segment—was proposed by C. F. Hochstetter.

Though sundry attempts at identifying various tissues, such as the fibro-vascular bundles, as the constituent individuals may be mentioned, those associated with the cell theory are of great importance. T. Schwendener would regard each leaf of the plant as a cell-community, in which the separate elements were like the bees of a swarm—a view virtually concurred in all essentials by M. Schleiden, K. Virchow and other founders of the cell theory. Yet, through the structure and functions of the tissues are ultimately and specially cellular, it is impossible to ignore the fact that, save in the very lowest organisms, these are subdivided into different tissue and larger aggregates, and form virtually the bricks of a building, these being added above. Of attempts to find the individual in the nucleus or the protoplasm granules it is unnecessary to speak further.

Far the theories of absolute individuality. The conception of relative individuality is perhaps that of Alphonse de Candolle and Schleiden, both of whom take the cell, the shoot and the multi-axial plant as forming three successive and subordinated categories. K. W. von Nägeli too recognized not only the necessity of establishing such a cell, organ, leaf, bud, leafy axis, plant organ, but the distinction between morphological and physiological individualities afterwards enunciated by Haeckel.

Passing over the difficulties which arise even among the Protoplastae we come to the Protozoa in which it has sometimes been said (Haeckel's Kalkschwämme) has raged over the individuality of sponges. While the older observers were content to regard each sponge-mass as an individual, a view in which J. N. Liederkern and other monographers subsequently concurred, the younger generation have held the view suggested by James Clark, and stoutly supported by Saville Kent, that the sponge is a city of amoeboi or insular individuals. H. J. Carter looked upon the various amöbic states as the true individuals, while the whole is only the individuality of a single exhalent apex, distinguish sponges into solitary and social.

For the higher animals the problem, though perhaps really even more difficult, is less prominent. As Haeckel points out, the earlier discussions and even the comparatively late essay of Johannes Müller take an almost purely psychological or at least a moral point of view; and the morphological aspect of the inquiry only came to light in the writings of Steenstrup and A. of W. (see Pterygota). Some monographers (see HYDROZOA), on the other hand, have regarded worms (see Platyhelminth) or Siphonophores (see HYDROZOA), had raised the difficulties that which botanists had so long familiar. With the rapid progress of embryology, too, arose new views. The desideratum of K. G. D'Orbigny, of Haeckel's "alternation of generations" as a mode of origin of distinct individuals by two methods, for him fundamentally similar, the sexual from the asexual, and the asexual from the unimpregnated "nurse" cell, a view concurred in by Steenstrup, and others, but keenly criticized by W. B. Carpenter and T. H. Huxley. In R. Leuckart's remarkable essay on polymorphism (1853) the Siphonophora were analysed into colonies, and their varied organs shown to be organized by the influence of the "dominant" shoot; while Steenstrup reduced to a case of polymorphism in development.

Leuckart further partly distinguished individuals of different orders, as well as between morphological and physiological individuals.
MORPHOLOGY

(Alter Haeckel)

animal, as Gallesio had done the plant, as the entire product of an impregnated ovum—the swarm of Aphides or free Medusae which in this way might belong to a single individual being termed Zooids. In Carus's System of Animal Morphology (1853) another theory was advanced, the vagaries in the statements which filled the appendages to the zeroth edition, and which form the subject of the present work. It is now, however, held beyond all doubt that the larva, in the very Origin, has the two main elements of the Polys, and these elements are represented by the higher seaweeds or the liverworts, from the thallus of which the axes and appendages of Monocotyledons and Dicotyledons are ingeniously derived. The shoot of a flowering plant being a chain of such outer segments, the aggregate of the fourth or higher order, and finally as a tree acquire a degree of composition too complex to be any longer defined.

In 1866 appeared a morphological classic, the Generelle Morphologie der Tiere, by W. de Candolle, in which several of the classes are considered as being aggregates of the third order, which may exhibit all degrees of development from the simple individual of the true Monera, up to the most highly integrated and individualized. Molluscs and vertebrates are regarded as aggregates of the second order.

arise merely, as Jäger expresses it, from that concentric lamination, or, with Ferrier, from that polymorphism of the members of the colony, which is associated with organic and social existence. The idea of the antime is omitted, as being essentially a pronomorphological conception (or of a medium, which, however, I believe to be a perfectly logical and possible one).

The next point is that the metamer is convenient to denote the secondary units of a linear tertiary individual; the term persona, however, seems unlikely to survive, not only on account of its connotations, but because it has been somewhat vaguely applied to aggregates of the second and third order; and the term colony, or, as I may be permitted to interpret them, the third order, which are not, however, integrated into a whole, and do not reach the full individuality of the next higher order. The term zoid is also objectionable as involving the idea of individualized organs, a view which is contradicted by the whole conception of the aggregates of the higher branching, which is above all accounted for as evolved of its homologue in Hydra, whereas the latter may be a degenerate form of the former. Passing to the vegetable world, here, as before, the cell is the unit of the first order, while aggregates representing almost every stage in the insensible evolution of a secondary unit are far more abundant than among animals. Complete unity of the second order can hardly be allowed to the thallus, which Spencer proposes to compound and integrate into a primary aggregate—higher plants; as in animals, the embryological method is preferable, both as avoiding gratuitous hypothesis and as leading to direct results. Such a unit is clearly presented by the embryo of higher plants in which the cell-aggregate is at once differentiated into the three primary axes and the azygous meristem, and the second order of capable separate existence, are not entitled to individual rank. The embryo, the bud, shoot or uniall plant, all thus belong to the second order of individuality, like the hydroid they resemble. Like the latter, it is formed by branching out from their low degree of integration. Such colonies can hardly be termed individuals of the third, much less of higher, order, at least without somewhat abandoning that unity of the whole which, in zoological morphology, is the subject of study.

Individuality of the second order is most fully reached by the flower—the most highly differentiated and integrated form of axes and appendages. Such a unit is the tetrad, or umbel, approximates to unity of the third order, to which a composite flower-head must be admitted to have attained and compounded. The plan of the flower-head is on the way to a yet higher stage. If, as seems probable, a nomenclature is indispensable for clear expression, it may be found most appropriate, since such usage is most in harmony with its inevitable physiologcal and psychical connotations, while the general individual of Gallesio and Huxley, common also to all the categories, may be designated, for purposes of economy, as ovum-cycle, the complete series of forms needed to represent the species being the species-cycle (though this coincides with the former save in cases where the sexes are separate, or polymorphism occurs). For such a peculiar case as Liriope pardinus, whose two tertiary forms of the same species coalesce, and still more for such heterogeneous individuality as that of a lichen, where a composite unit arises from the union of two altogether different forms—fungus and alga—yet additional categories and terms are required.

Promorphology. Just as the physical man constantly seeks to interpret the phenomena of function in terms of mechanical, physical, and chemical laws, so the morphologist is tempted to inquire whether organic as well as mineral forms are not alike reducible to simple mathematical laws. And just as the mathematician seeks idealized perfect mathematical form from an imperfect or fragmentary crystal, so the morphologist has frequently attempted to reduce the complex surfaces of organic beings to definite mathematical proportions. Canon Mosely (Phil. Trans., 1838) succeeded in showing, by a combination of measurement and mathematical analysis, that the curved surface of any turbinate or discoid shell might be considered as generated by the revolution, about the axis of the shell, of a curve, which continually varied its dimensions according to the law of the logarithmic spiral. For Goodrich this logarithmic spiral, now carved on his tomb, seemed a fundamental expression of organic curvature and the dawn of a new epoch in natural science—that of the mathematical investigation of organic growth. The second, and other elaborate mathematical representations of the body, its organs, and even its component cells seemed to yield, now the triangle, and again the tetrahedron, as the fundamental form. But such supposed results, savouring more of the Naturphilosophie than of sober mathematical inquiry, to discourage further inquiry and interest in that direction. Thus we find that even the best treatises on botany and zoology abandon the subject, satisfied with merely contrasting the simple geometrical ground-forms of crystals with the high and hopelessly complicated lines and surfaces of the organism.

But there are other considerations which lead up to a mathematical conception of organic form, those namely of symmetry and regularity. The less the organism is developed, botanists since Schleiden contenting themselves with throwing organisms into three groups—first, absolute or regular; second, regular and radiate; third, symmetrical bilaterally or zygomorphic—the last being capable of division into two halves only in a single plane, the body in two or more planes, the first in none at all. H. C. C. Burmeister, and more fully H. G. Brunn, introduced the fundamental improvement of defining the mathematical forms they sought not by the surfaces but by axes and their poles; and Haeckel has developed the subject with an elaborateness of detail and nomenclature which seems unfortunately not to have imposed its study and acceptance, but of which the main results may, with slight variations chiefly due to his own later views, be briefly outlined.

A. ANAXONIA: Forms descripted as polyamorpha, and consequently wholly irregular in form, e.g. Amoebe and many sponges.

B. AXONIA: Forms with definite axes.

1. Homostauria: forms with definite axes of the same order.

(a) Spheres, where an indefinite number of equal axes can be drawn through the middle point, e.g. Sphaeroum.

(b) Polyhedra, with a definite number of axes.

Of these, e.g. a hexahedron only one number occur in nature, for example, many radiolarians (fig. 3), polyhedral &c., and they are again classifiable by the number and regularity of their faces.

2. Stauraxonia, where, besides the main axes, a definite number of secondary axes are placed at right angles, and the stereometric ground-form becomes a pyramid.

Hence, we distinguish (a) those with simple spherical (Coccosidus) and cylinder (Pyrosoma) and (b) those with dissimilar poles, cone (Conus).

3. Stauronaxia, where, besides the main axes, a definite number of secondary axes are placed at right angles, and the stereometric ground-form becomes a pyramid. Here, we distinguish (a) those with poles similar, Stauraxonos homoea, where the stereometric form is the pyramid, and where we distinguish a basal, usually oral, pole from an apical, aboral or anal pole, and (b) those with dissimilar poles, homolopaca, where the stereometric form is a non-pyramidal figure, e.g. a cone.

4. Homostauria, where, besides the main axes, a definite number of secondary axes are placed at right angles, and the stereometric ground-form becomes a pyramid. Here, we distinguish (a) those with similar poles, Homostauraxonos homoea, where the stereometric form is the pyramid, and where we distinguish a basal, usually oral, pole from an apical, aboral or anal pole, and (b) those with dissimilar poles, homolopaca, where the stereometric form is a non-pyramidal figure, e.g. a cone.

5. Homostauria, where, besides the main axes, a definite number of secondary axes are placed at right angles, and the stereometric ground-form becomes a pyramid. Here, we distinguish (a) those with similar poles, Homostauraxonos homoea, where the stereometric form is the pyramid, and where we distinguish a basal, usually oral, pole from an apical, aboral or anal pole, and (b) those with dissimilar poles, homolopaca, where the stereometric form is a non-pyramidal figure, e.g. a cone.

6. Homostauria, where, besides the main axes, a definite number of secondary axes are placed at right angles, and the stereometric ground-form becomes a pyramid. Here, we distinguish (a) those with similar poles, Homostauraxonos homoea, where the stereometric form is the pyramid, and where we distinguish a basal, usually oral, pole from an apical, aboral or anal pole, and (b) those with dissimilar poles, homolopaca, where the stereometric form is a non-pyramidal figure, e.g. a cone.
the basal polygon is no longer regular but amphithec (\(\text{amphitec}=\text{double-edged}\)). Such a polygon has an even number of sides, and can be divided into symmetrical halves by each of two planes intersecting at right angles in the middle point, and thus dividing the whole figure into four congruent polygons. The longer of these axes may be termed lateral, the shorter the equatorial or dorso-ventral; and these two axes, along with the main axis, always define the three dimensions of space. Ctenophores (fig. 6) furnish examples of eight-sided amphithec pyramids, some Madreporo Corals of six-sided, Crucifers, some Meduse, and Centodes of four-sided amphithec pyramids.

In these forms the poles of the dorso-ventral and lateral axes are similar, and, according to the preceding Monaxon and Stauraxonia, the centre of the body is defined by a line; and they are therefore termed Centroaxonia, while the Protaxonia which are defined Centrostigmata. There are, however, other central point are called forms, and these the most complicated, in which the poles of at

---

least the dorso-ventral axis are unlike, and in which the body is thus defined not with reference to a line but to a median plane, as these have accordingly the name of monaxon.

Their ground-form is a polygon with an even number of sides, which can only be divided into two symmetrical halves by one median plane. It can be obtained by halving an amphithec pyramid of double the number of sides, and is consequently termed a half amphithec pyramid (fig. 7). The whole amphithec pyramid may be most conveniently obtained by the reduplication of the ground-form as if in a mirror. Of half amphithec pyramids there are again two forms, termed by Haeckel Amphipleurae and Zygo-

---

Frommorphology has thus shown that the reigning dogma of the fundamental difference of organic and mineral forms is false, and that a crystallography of organic forms is possible—the form of the solid or the cell-aggregating from the crystallographic plans of its more or less viscous state of aggregation, its inherited peculiarities, and its greater adaptability to the environment. The classification into bilateral and radiate forms which usually does duty for the general morphological plan is actually based on the principle that it is hopeless confusing essentially different forms, or at least must be rigidly restricted—the term radial to regular and double pyramids, the term bilateral to the Centropidea if not instead to disjugal forms and the term cubic to the solid, in which no more than two radialplane, and these at right angles to each other, are present. The stercorum ground-form is a half rhombic pyramid. Haeckel again divides these, according to the number of antimeres, into Tetrapleura and Dipleura.

---

The nature of morphological changes. The main forms of organic structure being analysed and classified and their stage of individuality being ascertained, the question next arises, by what morphological changes have they arisen, and into what categories can these modes of differentiation be grouped? They at first sight seem immensely varied, yet in reality there are not many. Generally they have been generalized for them the flower as ascending and descending metamorphosis, expansion and contraction of organs, &c.; but the first attempt at careful enumeration seems to be that of Auguste de St Hilaire, who recognized defects of development, adherences, excesses of production or “dédoublements,” metamorphosis and displacement of organs. Subsequent authors have variously treated the subject; thus Asa Gray enumerates as modifications of the flower—coalescence, adnation, irregularity, abortion, non-alternation or antiposition, multiplication, enation, unusual development of the axis, and other morphological modifications connected with fertilization. To these are obviously too numerous, as may be expected by any one who has ever been sufficiently occupied in the study of natural morphology. Thus Huxley, in discussing the arrangement of the Vertebrata, recognizes only three processes of modification, not only in the ancestral evolution of the Equidae, but in the individual development of the animals generally. In the arrangement of some parts in relation to others, (2) partial or complete suppression of certain parts, (3) coalescence of parts originally distinct. The particular form of excess of development which results from the repetition of a single term of the last three, due to partial or complete fusion of such repeated parts receive special treatment in the article Metamorphism.

---

**Nature of morphological correspondence—Categories of homology.**

Thus in the forms in which all these have been described, and which have been considered in the following paragraphs, the resemblance has been distinguished from that of physiological would be to examine the whole history of morphology; it must suffice to discuss the portion of the subject which has, as ever, served as a topic of dispute, and that is:—the division of the term homology. The term homology (E. homologie) has been applied to the resemblance of a part or organ determined by its relative position and connections with a part or organ in a different animal, the determination of which homology indicates that such animals are constituted in one common series, e.g. the lizard series, as determined by the homology of the pentadactyl foot. (a) Homology in the strictest sense of the term signifies a likeness or resemblance of parts between animals in the same line of descent; (b) homology, “representative or repetitive relation in the segments of the same skeleton” (demonstrated when general and special homologies have been determined); thus usually within the same series, and among animals of the same and different, derived from a common series.

---

Passing over the discussions of L. Agassiz and Bronn, of which the latter is criticized and partly incorporated by Haeckel, we find the last named (1) placing serial under general homology; (2) erecting of homology partially corresponding to that of individuals—(a) homostyly (of antimeres), hence distinct from that of Owen, (b) homodynamy (of metameres), (c) homonymy (of parts arranged on transverse axes); (3) defining species of homology with a special idea of the definition of homology above, as (2), but as applied to parts of different series, or to parts of the homologous or parallel series, as to the derived parts, and the parts of the homologous or parallel series, as to the derived parts, and the parts of the homologous or parallel series.

---

In 1870 this latter point was more fully insisted on by Ray Lankester, who, decomposing it into two others, proposed to supersede the term homology by homogeny, being the correlative of a combination of corresponding parts where homology was superinduced of position and structure in parts embryonically distinct. Thus, the fore limb of a mammal is homogenous with that of a bird, but the right and left ventricles of the heart of a vertebrate are homogenously, not homogenously, since the divergence of both groups from a uni-ventricular ancestry is in relation to similarity of physiological needs. St C. Mivart next proposed to retain homology as a generic term, with homogeny as homology as two species under it, and carried the analysis into detail, distinguishing at first twenty-five, but later fifteen, kinds of correspondence: (1) parts similar in function only, e.g. legs of lizard and lobster; (2) parts similar both in function and structure; (3) parts distinguished by homological relations; (4) parts of common descent, fore-limb of horse and rhinoceros; (5) parts of similar embryonic origin, whatever be their racial genetic relations, e.g. occipital processes and parietal; (6) parts of dissimilar embryonic origin, as limb girdle and foot; (7) parts of dissimilar origin, and in addition probably from an independent and common descent, legs of Diptera; (6) when, 8, 9, 10) laterally, vertically, serially, anteriorly and posteriorly and radially homologous parts; (11) subordinate serial homologies, e.g. joints of an antenna; (12 and 13) secondary and tertiary homologies; (14) general homologies (in Owen’s sense). In his Klebskunde Haeckel proposed to term homoply the truly phylogenetic homology in opposition to homomorph, to which genetic basis is wanting; and finally Von Jhering has published a repetition of Lankester’s view.

---

In this discussion, as in that of individuality, it is evident that we are dealing with numerous logical cross-divisions largely corresponding, no doubt, to the complex web of inter-relations presented by nature, yet remaining in need of disentanglement. Though we must set aside analyses of functional activity, the resemblances in external shape or geometric ground-form which correspond to these, e.g. Hydrozoa and Bryozoa, Fishes and Cetaceans, mimic
organisms, are nevertheless, as our historic survey showed, the first which attract attention; and these homoplastic or homomorphic forms, as Haekel has shown, come as fairly within the province of the promorphologist as do isomorphic crystals within that of his morphological colleague. But the development of the sense, whereby it would be considered "radial," "vertical," "lateral" homology, "homotypy of antimeres," and all questions of symmetry, for which Haekel's nomenclature of homaxonial, homoplastic, &c., is distinctly predicated, belongs not to the field or domain of the ordinary sense, we may next consider whether two organisms compared are of the same category of individuality—are homocategoric; and under this serial homology, for instance, would come as a matter of course the corresponding principle (2) from a unit-deme or unit of the intermediate order or orders of individuality. The parts and units thus recognized by ontogenetic research, respectively or successively homomorphic, homoeomorphic and homoclonal, may then conveniently be termed (indifferently save for considerations of priority) either "special homologists," "homogenous," "homophytic," or "homogenetic," in the language of phylogenetic theory. These three great classes of morphological homology—homoplastic, tectological, and embryological—may or may not coincide. But the complete homology, in which all forms of resemblance unite and from which they differentiate, is that expressed in the cell theory, or rather in that modern theoretical and experimental spirit which regards as "the greatest discovery in the natural sciences of modern times."

Orientation and Subdivision of Morphology.—The position of morphology, in the classification and statement of the facts of subdividing it cannot be discussed within these limits, although the latter is specially the subject of much disagreement. The position above assumed, that of including under morphology the whole subject of the organization and development of the cell, is that of Spencer, Huxley and most recent animal morphologists; botanists frequently, however, still use the term under its earlier and more limited significance (see Plants: Morphology). (P. G.; P. C. M.)

MORPHY, PAUL CHARLES (1837–1884), American chess player, was born in New Orleans, Louisiana, on the 22nd of June 1837, the son of Alonzo Morphy (1798–1836), and his wife, whose maiden name was Le Carpentier. The father, the son of a well-to-do Spanish immigrant, was a prominent jurist and legislator, and his brother Ernest, passionately fond of chess. Learning the moves from his father at the age of ten, Paul gave evidence of such extraordinary precocity that in less than two years he was able to defeat all the amateurs of his native city. While still at school he competed successfully with such strong players as Eugène Rousseau and the Hungarian master J. L. Lowenthal. He attended the Jesuit college at St Joseph, Spring Hill, Alabama, and applied himself to the study of the law, being admitted to the bar of Louisiana in 1858. During the autumn of 1857 he took part in the first American chess congress at New York, winning the first prize from sixteen competitors, including the well-known L. Paulsen. Morphy went to Europe in the spring of 1858 and entered upon a series of triumphs, his regular matches and blindfold play, that proved him to be one of the best players of the time. The winter of 1858–1859 was passed in Paris, where he was destined to gain his greatest triumphs, practically winning the championship of the world by beating Adolf Anderssen, champion of Germany, by a score of 7–2, with two games drawn. Another feat was his simultaneous blindfold match against eight strong French players, six of whom he defeated. At this time he was in his twenty-second year. Returning to the United States in 1859, he intended to establish himself in the practice of the law at New Orleans, but the outbreak of the Civil War frustrated these plans. His devotion to chess had already begun to affect his health. He spent the year 1863 in Paris, returning to New Orleans in 1864, but his health was now permanently impaired. He became insane, and at last he died in New Orleans in 1884.

See the Preface of J. M. Ede (New York, 1856); Morphy's Games, edited by J. Lowenthal (New York, 1860); Paul Morphy, by Max Lange (Leipsig, 1881).

MORRILL, JUSTIN SMITH (1807–1898), American political leader and financier, was born at Strafford, Vermont, on the 14th of April 1810. He was a clerk in a store at Strafford in 1828–

1828, and at Portland, Maine, in 1828–1831, and was a merchant and then a farmer in his native town in 1831–1833. He was elected to the national house of representatives as an anti-slavery Whig in 1842, and soon afterwards joining the new Republican party, and served in the house from 1835 until 1867. From 1867 until his death in Washington on the 28th of December 1898 he represented Vermont in the Senate. In the house he was continuously a member of the ways and means committee (of which he was chairman in 1865–1867), and in the Senate of the finance committee (of which he was chairman in 1877–1879, 1885–1893 and 1893–1898). Soon after entering Congress he became the acknowledged leader of the protectionists, and at the request of John Sherman, then chairman of the ways and means committee, he prepared a new tariff bill, which was introduced in the house in March 1860. This relatively conservative bill, which substituted in many instances ad valorem for specific duties, and was intended by its author to be a revenue as well as a protective measure, were added many amendments which made the bill more strongly protectionist, and in some cases were vigorously opposed by Morrill. The bill was finally passed by the Senate on the 20th of February 1861, and was signed by President Buchanan on the 2nd of March following. Morrill is probably best known as the author of the Land Grant Act of 1862, which led to the development of the highly important system of state educational institutions, aided by the Federal government. On the 14th of December 1857, Morrill introduced in the house a bill "donating public lands to the several states and Territories which may provide colleges for the benefit of agriculture and the mechanic arts." This bill passed both houses, but was vetoed in February 1859 by President Buchanan on the ground that it would cause friction between the states, that it would be uneconomical, that it might encourage fraudulent speculation, that it would injure existing institutions, and that it was unconstitutional. A similar bill was introduced in the house on the 16th of December 1861, and five months afterwards was presented to the Senate by Benjamin Wade of Ohio. The measure had a negative report from committee in the house, and was strongly opposed in the Senate; but it passed both branches, and on the 2nd of July 1862 was signed by President Lincoln. This measure provided for the foundation and maintenance of colleges "where the leading object shall be, without excluding other scientific and classical studies, and including military tactics [which had not been included in the original bill], to teach such branches of learning as are related to agriculture and the mechanic arts...in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions in life." In 1850 Morrill introduced in the Senate the so-called "Second Morrill Act," under which $25,000 is given annually by the Federal government to each of the "land-grant" colleges.

MORRIS [MORRISON], CLARA (1840— ), American actress, was born in Toronto, Ontario, and at the age of seventeen joined a stock company in Cleveland, Ohio. Her first New York appearance (1870) was under August Daly in an adaptation of Wilkie Collins's Man and Wife; and she won considerable success as Cora in L'Article 47, Camille, Miss Multon and similar emotional parts. In 1874 she married Frederick C. Harriott, and soon afterwards began to write novels and to contribute to magazines. She published her Life on the Stage in 1901, and Life of a Star in 1906.

MORRIS, GOUGNEUR (1752–1816), American statesman, was born in the old Morrisania manor house, in what is now the city of New York, on the 31st of January 1752. He graduated at King's College (now Columbia University) in 1768, studied law, and was admitted to the bar in 1771. New York, then in the throes of the political disturbances which preceded the outbreak of the War of American Independence, he seized the good opportunity for a public career, and Morris had the aristocratic connexions which tradition required. An extreme aristocrat

1 His great grandfather, RICHARD MORRIS, having fought in Cromwell's armies, emigrated to America on the restoration of Charles II., and founded the manor of Morrisania, in what was then New Netherland. His grandfather, LEWIS MORRIS (1671–1746), inherited this
in his political views, he distrusted the democratic tendencies of the Whigs, but a firm belief in the justice of the American cause caused him to part company with his Whig friends. His half-brother, Staats Long Morris (1728-1800), was a Tory, fought in the British army, and became a major-General. Gouverneur served in the New York Provincial Congress in 1776-1777, was perhaps the leading advocate in that body of a declaration of independence, and after the Congress had become (July 1776) the "Convention of the Representatives of the state of New York," he served on the committee of that body which prepared the first draft of the state constitution. He served in the Continental Congress in 1777-1779, and was enthusiastic in his support of Washington. In 1778 he was selected chairman of the committee to treat with Lord North's conciliation commissioners, and as such presented the famous report, adopted by a unanimous vote of Congress, which declared that the recognition of independence must precede any negotiations for peace. He settled in Philadelphia as a lawyer, and in February 1780 he published in Philadelphia a series of essays on finance, in which he criticized the legality of legal-tenders, denounced laws passed for the benefit of the debtor class, and urged the people to tax themselves for the common defense. In 1781-1783 he was defeated for the seat in Congress by his brother Morris (q.v.), superintendent of finance. In 1782 he prepared an elaborate report on the coinage, suggesting the use of the decimal system and of the terms dollar and cent. With some modifications introduced by Jefferson, notably the adoption of a higher unit of value (the dollar instead of one-tenth of a cent), this plan constitutes the basis of the present American system.

MORRIS, J.—MORRIS, SIR LEWIS

was one of Pennsylvania's representatives in the constitutional convention of 1787, and took an active part in the debates. His influence was weakened, however, by his cynicism and by his ultra-aristocratic views. He favoured a strong executive holding during good behaviour, an aristocratic senate appointed by the president for life, and the restriction of the suffrage to freeholders. The struggle which the frontier settlers of Pennsylvania had made in the state legislature to secure unlimited issues of paper money and the enactment of laws favourable to the debtor class prejudiced him against the West, and he tried to introduce into the constitution a clause guaranteeing forever the political supremacy of the states east of the Alleghanies. He was finally defeated in 1787 and 1788 by presenting to Governor Sparks and his party the proposal that the legislature should elect the president. He also gave able support to the nationalist and anti-slavery factions in the convention. He was the member of the committee of revision selected to draft the constitution in its final form, and that document is a monument to the vigour and simplicity of his literary style. In 1787 he bought Morrisiana from Staats Long Morris, and returned to New York to live.

He went to France in February 1789 on private business, and remained abroad for nine years, passing most of the time in Paris, London, and the German capitals. In 1792 he acted as financial agent in a daring attempt to secure the escape of the king and queen from Paris. He was appointed United States minister to France in 1792, and was the only representative of a foreign country who remained at his post throughout the Reign of Terror; but his ill-concealed attitude of hostility to the Revolution gave offence, and in return for the recall of Genet, at the request of the United States, the French government, in 1794, asked for the recall of Morris. Business and pleasure, however, still detained him in Europe for four years longer. He returned to New York in 1798, resumed the practice of his profession, re-entered politics, and sat in the United States Senate as a Federalist from 1800 to 1803. As early as 1801 Morris became interested in projects for improving the communication between the Hudson river and Lake Erie, and from 1810 to 1816 he was chairman of the board of canal commissioners, which after exploring the country prepared plans for the Erie Canal. He was bitterly opposed to the war of 1812, and openly advocated the formation of a northern confederacy to escape the rule of the "Virginia dynasty." He died at Morrisiana on the 6th of November 1816.

His half-brother, LEWIS MORRIS (1726-1798), a signer of the Declaration of Independence, was educated at Yale, served in the Continental Congress from 1775 until early in 1777, and went on a mission to the western frontier in 1777 to win over the Indians from the British to the American side. He joined the army as brigadier-general of militia in June 1778, and served in the New Jersey campaign. In 1780 he was again in the army, and in 1781 and 1782, as superintendent of finance (1710-1719), he proved to his battalion of his profession, re-entered politics, and sat in the United States Senate as a Federalist from 1800 to 1803. As early as 1801 Morris became interested in projects for improving the communication between the Hudson river and Lake Erie, and from 1810 to 1816 he was chairman of the board of canal commissioners, which after exploring the country prepared plans for the Erie Canal. He was bitterly opposed to the war of 1812, and openly advocated the formation of a northern confederacy to escape the rule of the "Virginia dynasty." He died at Morrisiana on the 6th of November 1816.

See The Diary and Letters of Gouverneur Morris (2 vols., New York, 1888), edited by Anne Cary Morris; Jared Sparks, Life of Gouverneur Morris (3 vols., Boston, 1832), the first volume being a biography and the second and third containing Morris's miscellaneous writings and addresses; and Theodore Roosevelt, Gouverneur Morris (Boston, 1888), in the "American Statesmen" series.

MORRIS, JOHN (1810-1886), English geologist and palaeontologist, was born at Homerton, London, on the 10th of February 1810. He was brought up to the business of a pharmaceutical chemist. Early in life he published observations on the Tertiary and Post-Tertiary deposits in the Thames valley, and on fossil plants and various invertebrata, in the Magazine of Natural History, the Annals of Nat. Hist. and other journals. In 1845 he issued his Catalogue of British Fossils (2nd ed., 1854), a work of essential service to geology. He was also author (with John Lycett) of A Monograph of the Mollusca from the Great Oolite (Palaeontographical Soc., 1850-1851). In 1855 he became professor of Geology in University College, London, a post which he held until 1877. In 1868-1870 and 1877-1878 he was president of the Geologists' Association. He was awarded the Lyelli medal by the Geological Society in 1876, and was Hon. M.A. of Cambridge in 1878. In 1879 he retired from active services as deputy Woodwardian professor during the final illness of Sedgwick. He died in London on the 10th of January 1886.

MORRIS, SIR LEWIS (1833-1907), British poet, eldest son of Edward William Morris and Sophia, daughter of John Hughes of Carmarthen, was born at Penbryn in 1833. His great grandfather, Lewis Morris (1700-1765), had been a well-known Welsh poet and antiquary. He was educated at Sherborne School and Jesus College, Oxford, where he took the first classes in classics (1853 and 1855). He won the chancellor's prize for an English essay in 1858, was called to the bar in 1861, and elected hon. fellow of his old college in 1877. He practised for twenty years as a conveyancing counsel, retiring from active legal work in 1881. He was energetic on behalf of educational movements in Wales, and contested Welsh constituencies in the Liberal interest, but without success. He was knighted in 1896, and became also a Jubilee-medallist and Knight of the Redeemer of Greece. Comparatively late in life Sir Lewis Morris made his appearance as a writer of verse with three series of miscellaneous poems, issued in London as Songs for a Summer, published respectively in 1872, 1874 and 1878. These little volumes are notable for having a refined taste and a gentle metrical fluidity, which soon won for his work considerable popularity. In 1875 and 1877 he made a more important venture with The Epic of Hades, an attempt to retell the stories of Hellenic mythology with a certain modern and allegorical setting. This work, though it is somewhat strained in sentiment and is not free from artistic infelicities, contains his best verse and has passages of undeniable force and effect. His later work follows too closely upon the influence of Tennyson, from which he is never altogether free; but his earnest
MORRIS, R.—MORRIS, W.

interests and engaged extensively in western land speculation. At one time or another he owned wholly or in major part nearly the entire western half of New York state, two million acres in Georgia, and about one million each in Pennsylvania, Virginia, and South Carolina. The slow development of this property, the failure of a London bank in which he had funds invested, the erection of a palatial residence in Philadelphia, and the dishonesty of one of his partners, finally drove him into bankruptcy, and he was confined in a debtors' prison for more than three years (1798–1801). He died in Philadelphia on the 7th of May 1806.

The best biography is E. P. Oberholtzer's Robert Morris, Patriot and Financier (New York, 1903), based upon the Robert Morris papers in the Library of Congress; see also W. G. Sumner's The Financier and the Finances of the American Revolution (New York, 1891).

MORRIS, WILLIAM (1834–1896), English poet and artist, third child and eldest son of William Morris and Emma Shelton, was born at Elm House, Walthamstow, on the 24th of March 1834. His grandfather was a respected tradesman in Worcester, and his father, who was born in that town in 1797, came up to London in 1820, and entered the office of a firm of discount brokers, in which he afterwards assumed a partnership. As a child the poet was delicate but studious. He learnt to read very early, and by the time he was four years old was familiar with most of the Waverley novels. When he was six the family moved to Woodford Hall, where new opportunities for an out-of-doors life brought the boy health and vigour. He rode about Epping Forest, sometimes in a toy suit of armour, became a close observer of animal nature, and was able to recognize any bird upon the wing. At the same time he continued to read whatever came in his way, and was particularly attracted by the stories in the Arabian Nights and by the designs in Gerard's Herbal. He studied with his sisters' governess until he was nine, when he was sent to a school at Walthamstow. In his thirteenth year his father died, leaving the family well-to-do; the home at Woodford was broken up, as being unnecessarily large; and in 1848 William Morris went to Marlborough, where his father had bought him a nomination. Morris was at the school three years, but got very little good from it beyond a taste for architecture, fostered by the school library, and an attraction towards the Anglo-Catholic movement. He made but slow progress in school work, and at Christmas 1851 was removed and sent to a private tutor for a year. In June 1852 he matriculated at Exeter College, Oxford, but, as the college was full, he did not go into residence till January 1853. He remained in close friendship with his fellow students, and spent all his life, foremost among whom were Edward Burne-Jones, who was a freshman of his year, and a little Birmingham boy at Pembroke. They were known among themselves as the "Brotherhood"; they together theology, ecclesiastical history, medieval poetry, and, among moderns, Tennyson and Ruskin. They studied art, and fostered the study in the long vacations by tours among the English churches and the Continental cathedrals. Moreover, Morris began at this time to write poetry, and many of his first pieces, afterwards destroyed, were held by sound judges to be equal to anything he ever did. Both Morris and Burne-Jones had come to Oxford with the intention of taking holy orders, but as they felt their way they both came to the conclusion that there was more to be done in the direction of social reform than of ecclesiastical work, and that their energies would be best employed outside the priesthood. So Morris decided to become an architect, and for the better propagation of the views of the new brotherhood a magazine was at the same time projected, which was to make a speciality of social articles, besides poems and short stories.

At the beginning of 1856 the two schemes came to a head together. Morris, having passed his finals in the preceding term, was entered as a pupil at the office of George Edmund Street, the well-known architect; and on New Year's Day the first number of The Oxford and Cambridge Magazine appeared. The expenses of this very interesting venture were borne entirely
by Morris, but after the issue of No. 1 he resigned the formal editorship to his friend Fulford. Many distinguished compositions appeared in its pages, but it gradually languished, and was given up after a year's experiment. The chief immediate result was the friendship between Morris and Dante Gabriel Rossetti (q.v.), which sprang up from a successful attempt to secure Rossetti as a contributor. In the summer of 1856 Street removed to London, and Morris accompanied him, working very hard both in and out of office hours at architecture and painting. But Rossetti persuaded him that he was better suited for a painter, and after a while he devoted himself exclusively to that branch of art. It was in the summer that the two friends visited Oxford, and finding the new Union debating-hall in course of construction, offered to paint the bills. Seven artists volunteered help, and the work was hastily begun. Morris worked with feverish energy, and on finishing the portion assigned to him proceeded to decorate the roof. The work was done too soon and too fast, the colours began to fade at once, and are now barely decipherable; but the broken designs, so long as any vestige remains, will always be interesting as a relic of an important aesthetic movement and as the first attempt on Morris's part to express decorative art. The results were published as The Defence of Guenevere, which was almost unnoticed by contemporary criticism, but is now recognized as one of the pearls of Victorian poetry.

On 26th April 1859 Morris married Jane Burden, a beautiful Oxford girl, who had sat to him as a model, and settled temporarily at 41 Great Ormond Street, London. Meanwhile he set about building for himself at Upton a house which was to be the embodiment of all his principles of decorative art. Furniture, decorations, household utensils and every article of daily use were specially designed, and in the summer of 1860 the house was ready for occupation. The furnishing of it had suggested a fresh activity; Morris now determined to embark upon decoration as a career. A small company was formed, consisting of D. G. Rossetti, Philip Webb, Burne-Jones, Madox Brown, Faulkner and Marshall, and in January 1862 started business under the title of Morris, Marshall, Faulkner & Co., with offices at 8 Red Lion Square. The prospectus set forth that the firm would undertake church decoration, carving, stained glass, metalwork, paper-hanging, and the designing of costumes. The business, after inevitable vicissitudes, flourished, but the "house beautiful" at Upton proved to be unhealthily situated. Serious illness obliged the family to remove to town, and in November 1863 they resettled at 26 Queen Square, Bloomsbury. Morris was now unceasingly busy, but he found time also for literature. In June 1867 he published The Life and Death of Jason, which was at once successful; and in April 1868 the first two parts of The Earthly Paradise. The rest of this wonderful storehouse of poetic romance appeared in two volumes in 1869 and 1870. In the following year he was again looking for a country house, and lighted upon Kelmscott manor house, in the Upper Thames valley, which he took at first in joint-tenancy with Rossetti and used principally as a holiday home. In 1872 appeared Love is Enough, structurally the most elaborate of his poems for its combination of the epic and dramatic spirits; and in the autumn he began to translate the shorter Icelandic sagas, to which his enthusiasm had been directed by two inspiring journeys to Iceland. Business worries, however; interrupted him; it was found necessary to reconstruct the company owing to its having grown out of proportion with the existing division of profit and labour. Long negotiations ensued, and in March 1875 the old firm was dissolved. Morris now became sole manager and proprietor, although the other members of the old firm continued, in varying degrees, to give him the advantage of their assistance and advice.

Meanwhile the epic mood had possessed Morris very strongly, and, in addition to his work upon the sagas, he had actually finished and (in 1875) published a verse translation of the Aeneid, which is interesting rather for its individuality than for any fidelity to the spirit of the original. In the following year appeared Sigurd the Volsung, a version full of heroic vigour, movement and vitality, and somewhat too lengthy and incoherent in design to preserve the epic interest intact to the British taste. This splendid burst of poetic activity, however, had raised him to a place among the first poets of his time; and in 1877 an attempt was made to induce him to accept the professorship of poetry at Oxford. But he felt himself lacking in the academic spirit, and wisely declined. At this time a fresh outlet for his energy was furnished by his foundation in 1877 of the Society for the Protection of Ancient Buildings, which sprang into being as a practical protest against a scheme for restoring and reviving Tewkesbury Abbey. He began, too, to take an active interest in politics over the Eastern Question, but his enthusiasm was at the moment a flash in the pan. Finding that events were going against his judgment, Morris, as was so often the case with him, shrugged his shoulders and broke free from the movement.

Still, although he found it hard to sit close to a definite party, Morris continued to be spasmodically interested in political movements. During the next few years, indeed, the interest gained ground with him steadily. He became treasurer of the National Liberal League in 1879, but after the Irish controversy of 1885 left the Liberal party and drifted further and further into Socialism. For ten or twelve years this movement had been gaining ground in England, and the Social Democratic Federation was formed in 1881. In January 1883, within a week of his election to an honorary fellowship at Exeter, Morris was enrolled among its members. Thenceforward for two years his advocacy of the cause of Socialism absorbed not only his spare time, but the thought and energy of all his working hours. For it he even neglected literature and art. In March 1883 he gave an address at Manchester on "Art, Wealth and Riches"; in May he was elected upon the executive of the federation. In September he wrote the first of his Chants for Socialists. About the same time he shocked the authorities by pleading in University Hall for the wholesale support of Socialism among the undergraduates at Oxford. Nevertheless, the federation began to weaken. At the franchise meeting in Hyde Park in 1884 it was unable to get a hearing. Morris, however, had not yet lost heart. Internal dissensions in 1884 led to the foundation of the Socialist League, and in February 1885 a new organ, Commonwealth, began to print Morris's splendid rallying-songs. Still, differences of opinion and degree prevented concerted action; and when, after the Trafalgar Square riots in February 1886, Morris resuscitated with the anarchic section he was denounced by the advanced party and ever afterwards was regarded with suspicion. In 1889 he was deposed from the management of Commonwealth, and gradually lost all confidence in the movement as an active force.

Long before that time, however, Morris had returned to the paramount interests of his life—to art and literature. When his business was enlarged in 1881 by the establishment of a tapestry industry at Merton, in Surrey, Morris found yet another means for expressing the medievalism that inspired all his work, whether on paper or at the loom. In 1887 he published his translation of the Odyssey, which had many of the qualities and defects of his Aeneid, and is much more interesting as an experiment than valuable as a "Homerian echo. In the Commonwealth appeared Aegisthus, now, published in book form in 1893, describing an England in which the principles of communism have been realized. He then added another to his many activities; he assumed a direct interest in typography. In the early seventies he had devoted much attention to the arts of illumination and calligraphy. He himself wrote several manuscripts, with illuminations of his own devising. From this to attempts to beautify the art of modern printing was but a short step. The House of the Wolfings, printed in 1889 at the Chiswick Press, was the first essay in this direction; and in the same year, in The Roots of the Mountains, he carried his theory a step further. Some fifteen months later he added a private printing-press to his multifarious occupations, and started upon the first volume issued from the Kelmscott Press, his own Glittering Plain. For the last few years of his life this new interest remained the
absorbing one. A series of exquisite books, which gain in value every year, witnesses to the thorough and whole-hearted fashion in which he invariably threw himself into the exigencies of his life-work.

The last years of his life were peacefully occupied. He was sound as to whether he would accept the laureateship upon the death of Tennyson, but declined, feeling that his tastes and his record were too remote from the requirements of a court appointment. His last piece of work, the crowning glory of his printing-press, was the Kelmscott Chaucer, which had taken nearly two years to print, and fully five to plan and mature. It was finished in June 1896, and before it was in his hands he already knew that his working day was over. His vigour had been slowly declining for some time, and he sank gradually during the autumn. He died at the suburb of Little Kelmscott, near the Thames, on November 30, 1896, and was buried in the churchyard, followed to the grave by the workmen whom he had inspired, the members of the league which he had supported, the students of the art gild he had founded, and the villagers who had learnt to love him.

Essentially the child of the Gothic revival, he had put an ineffaceable stamp on Victorian ornament and design, his place being that of a follower of Ruskin and Pugin, but with a greater practical influence than either. In house decoration of all kinds—furniture, wall-papers and hangings (which he preferred to paper), carpet-weaving, and the painting of glass and tiles, needlework, tapestry—he formed a school which was dominated by his protest against commercialism and his assertion of the necessity for natural decoration and pure colour, produced by hand instead of machinery, and the beauty irrespective of cheapness or quickness of manufacture (see ARTS AND CRAFTS).

The truest criticism of William Morris is that attributed to his friend, the poet Swinburne, who said that he was always more truly inspired by literature than by life. His Socialism, though it made a brave show at times, was at heart a passionate enthusiasm for an inaccessible artistic ideal. Morris, indeed, was not primarily interested in men at all, but in objects. His poetry deals, it is true, with the human passions, but the emotion is always seen as in a picture; he is more concerned with the attitude of the group than with the realization of a character. He had very little adaptability in dealing with his fellows; the crowd, as a crowd, fired his enthusiasm, but he was unable to cope with the individuals that composed it. Many of his colleagues bear within them the same character as Morris and the vitality of the individualism that he so deeply admired. There is always, for them, a field of human interest which he never entered.

The one failing of his art: it is also the shortcoming of his poetry. Granted this, there is left an immense amount that will always command admiration. The spirit of beauty breathes in every line; a sense of music and of colour is everywhere abundant; the reader moves, as it were, under a canopy of apple-blossom, over a flower-starred turf, to the faint harmony of virginals. Nor does the poet lack power and vigour when an adventurous story is to be told. The clash of arms breaks upon his pagan paradise with no uncertain sound; he is swift in narrative, breathless in escape. And over all hangs the faint atmosphere of medievalism, of an England of green gardens and grey towers, of a London "small and white and clean," of chivalry and adventure. Every break in the rhythm has also to remember the historical value of Morris's literary influence, following upon the prim domesticities of early Victorian verse, and breaking in upon Tennyson's least happy phase of national homeliness.

MORRIS, Morris, R.

MORRIS, or MORRIS-DANCE (Sp. Morisco, Moorish), an old English dance, which is said by various authorities to have been introduced by John of Gaunt from Spain or borrowed from the French or Flemings. That it was a development of the morisco-dance or Spanish fandango is not invalidated by the fact that the morisco was for one person only, for, although latterly the morris-dance was represented by various characters, uniformity in this respect was not always observed. There are few references to it earlier than the reign of Henry VII., but it would appear that in the reign of Henry VIII. it was an almost essential part of the principal village festivities. In earlier times it was usually danced by five men and a boy dressed in a girl's habit, who was called Maid Marian. There were also two musicians; and, at least sometimes, one of the dancers, the "morris man," was garbed richly with a cloak and a hood as "foreman of the morris." The garments of the dancers were ornamented with bells tuned to different notes so as to sound in harmony. Robin Hood, Friar Tuck and Little John were characters extraneous to the original dance, and were introduced when it came to be associated with the May-games. At Betley, in Staffordshire, there is a painted window, of the time of Henry VIII. or earlier, portraying the morris—the characters including Maid Marian, Friar Tuck, the hobby-horse, the piper, the tabourer, the fool and five other persons apparently representing various ranks or callings. The hobby-horse, which, latterly at least, was one of the principal characters of the dance, consisted of a wooden figure attached to the person of the actor, who was covered with trappings reaching to the ground, so as to conceal his feet. The morris-dance was abolished along with the May-games and other festivities by the Puritans, and, although revived at the Restoration, the pageant gradually degenerated in character and declined in importance. Maid Marian latterly was personated by a clown, who was called Malkin or Marykin. The interest of the subject has revived in recent years in connexion with the new movements associated with folk-music generally.

MORRIS, Arthur (1863— ), English novelist, was born in Kent on the 1st of November 1863. He was for a short time a clerk in the Customs and Excise, but left it to go to Cambridge. He had already published scattered tales and sketches of low life in London when W. E. Henley, with whom he was connected as a contributor to the National Observer, suggested their publication in volume form. Tales of Mean Streets (1894) immediately attracted attention, and this was followed by A Child of the Jago (1896), the scene of which is laid between High Street, Shoreditch, and Bethnal Green. Running Murrell (1900), The Hole in the Wall (1902), and the detective stories, Martin Hewitt, Investigator (1894), which had sequels in 1894 and 1896, and The Green Eye of Gorma, are among his other works.

MORRIS, Richard James (1795-1874), English astronomer, commonly known by his pseudonym "Zadkiel," was born on the 15th of June 1795. He served in the Royal Navy, but in 1830 he left it to turn his attention to the stars. In 1831 he dedicated himself to the study of astronomy, and in 1831 issued The Herald of Astrology, subsequently known as Zadkiel's Almanac. In this annual pamphlet Morrison, over the signature "Zadkiel Tao-Sze," published predictions of the chief events of the coming year. In 1863 Morrison brought a libel action against Admiral Sir Edward Belcher, who had accused him of obtaining money by charlatanism in the form of crystal-gazing. He was awarded twenty shillings damages, but was deprived of his costs. Morrison died on the 4th of April 1874.

MORRIS, Robert (1782-1834), the first Protestant missionary to China, was born of Scottish parents at Buller's Green, near Morpeth, on the 5th of January 1782. After receiving an elementary education in Newcastle, he was apprenticed to a lastmaker, but his spare hours were given to theology, and in 1803 he was received into the Independent Academy at...
Hoxton. In the following year he offered his services to the London Missionary Society, and after he had attended David Bogue's college at Gosport and studied Chinese under a native teacher, he was appointed to Canton in 1816. After a year of much hardship he became translator to the East India Company's factory there in 1809, and worked at a Chinese Grammar and a translation of the New Testament, both published in 1814. In 1817 he published A View of China for Philological Purposes, and his translation of the Old Testament (in which William Milne collaborated) was completed in the following year. His next enterprise was the establishment (1820) of an Anglo-Chinese college at Malacca for "the reciprocald cultivation of Chinese and European literature." Here too were trained native Chinese evangelists who could proceed to the mainland and carry on Christian work with comparative immunity. In 1821 Morrison's Chinese Dictionary, in six 4to volumes, a monumental work, was published by the East India Company, at a cost of £12,000. Leaving China at the close of 1823, Morrison spent two years in England, where he was elected a fellow of the Royal Society. Returning to China in 1826, he set himself to promote education and to prepare a Chinese commentary on the Bible and other Christian literature. He died at Canton in 1834, and his name is forever associated with the work accomplished by his grammars and dictionary; and his establishment of a dispensary, manned by a native who had learned the main principles of European treatment, marks him out as the forerunner of modern medical missions. His Memoirs, compiled by his widow, were published in 1839. See also R. Lovett, History of the London Missionary Society, vol. ii. ch. xix.; C. S. Hore, The Story of the L. M. S. ch. v.; Townsend, Robert Morrison (1886).

MORRISTOWN, a town and the county-seat of Morris county, New Jersey, U.S.A., on the Whippaunee river, 31 m. (by rail) W. of New York City. Pop. (1890) 8156; (1900) 11,437; (1910 census) 12,307. It is served by the Delaware, Lackawanna & Western, the New Jersey & Pennsylvania and the Morristown & Erie railways. Morristown is situated on a table-land surrounded by picturesque hills. It is primarily a residential suburb of New York, and has many handsome residences and a number of large estates. Near its centre is a public park, in which is a soldiers' monument (59 ft. in height). At Morristown, about 4 m. to the north, is a state hospital for the insane (1876).

Morristown, officially named in 1740 in honour of Lewis Morris (1671-1746), then governor of New Jersey, and grandfather of Governor Morris, was settled about 1710, under the name of West Hanover, by Puritans, who were attracted here by the presence of iron ore. From January to May 1777, and again from December 1779 to June 1780, Morristown was occupied by the American army under Washington. Behind the court-house is the site of Fort Nonsense, built at Washington's orders, largely to keep his soldiers employed. In December 1777-January 1780 General Benedict Arnold was tried before a court martial presided over by General Robert Howe (1732-1785) in the Dickerson tavern here, still standing. In Morristown General Washington's sword (almost completely destroyed by fire in 1809), was made part of the machinery of the "Savannah," the first steamboat that crossed the Atlantic, and here Samuel F. B. Morse and Alfred Vail completed the invention of the electric telegraph. Morristown was incorporated as a town in 1835.

See A. M. Sherman, Historic Morristown, New Jersey: The Story of its First Century (Morristown, 1905) and Julia K. Colles, Authors and Writers Associated with Morristown (Morristown, 1893).

MORSE, SAMUEL FINLEY BRESEE (1791-1872), American artist and inventor, was born at Charlestown, Massachusetts, on the 27th of April 1791, son of Jedidiah Morse (1761-1826), Congregational minister there and a writer on geography, and a grandson of Samuel Finley, president of the college of New Jersey. At the age of fourteen he entered Yale College, where he graduated in 1810 and where under the instruction of Jeremiah Day and Benjamin Silliman he received the first impulse towards electrical studies. In 1811 Morse, whose tastes during his early years led him more strongly towards art than towards science, became the pupil of Washington Allston, and accompanied his master to England, where he remained four years. His success at this period as a painter was considerable. In 1823 he was one of the founders of the National Academy of Design, and was its first president, from 1826 until 1842. The year 1827 marks the revival of Morse's interest in electricity. It was at that time that he learned from J. F. Dana of Columbia College the elementary facts of electromagnetism. As yet, however, he was devoted to his art, and in 1829 he again went to Europe to study the old masters.

The year of his return, 1832, may be said to close the period of his artistic and to open that of his scientific life. On board the packet-ship "Sully," while discussing one day with his fellow-passengers the properties of the electromagnet, he was led to remark: "If the presence of electricity can be made visible in any part of the circuit, I see no reason why intelligence may not be transmitted by electricity." In a few days he had completed rough drafts of the necessary apparatus, which he displayed to his fellow-passengers. During the twelve years that followed Morse was engaged in a painful struggle to perfect his invention and secure for it a proper presentation to the public. In poverty at this period he was manaced with threats of imprisonment, his models, moulds and castings, were broken, and his name denounced as a "mouldsman," denying himself the common necessities of life. It was not until 1836 that he completed any apparatus that would work, and finally, on the 2nd of September 1837, the instrument was exhibited to a few friends in the building of the university of the City of New York, where a circuit of 1700 ft. of copper wire had been set up, with such satisfactory results as to awaken the practical interest of the Messrs. Vail, iron and brass workers in New Jersey, who thenceforth became associated with Morse in his undertaking. Morse's petition for a patent was soon followed by a petition to Congress for an appropriation to defray the expense of subjecting the telegraph to actual experiment over a length sufficient to establish its feasibility and demonstrate its value. The committee on commerce, to whom the petition was referred, reported favourably. Congress, however, adjourned without making the appropriation, and meanwhile Morse sailed for Europe to take out patents there. The trip was not a success. In England his application was refused, and, while he obtained a patent in France, it was subsequently appropriated by the French government without compensation to himself. His applications also with Russia proved futile, and after a year's absence he returned to New York. In 1843 Congress passed the long-delayed appropriation, steps were at once taken to construct a telegraph from Baltimore to Washington, and on the 24th of May 1844 it was used for the first time. In 1847 Morse was compelled to defend his invention in the courts, and successfully vindicated his claim to be called the original inventor of the electromagnetic recording telegraph. In 1858 the representatives of Austria, Belgium, France, the Netherlands, Piedmont, Russia, the Holy See, Sweden, Tuscany and Turkey appropriated the sum of 400,000 francs in recognition of the use of his instruments in those countries. He died on the 2nd of April 1872, at New York, where his statue in bronze now stands in the Central Park. (See TELEGRAPH.) He introduced into America Daguerre's process of photography, patented a marble-cutting machine in 1823, and in 1842 made experiments with telegraphy by a submarine cable.

See S. Irenaeus Prime, Life of S. F. B. Morse (New York, 1875).

MORSE, the ornamented brooch by which a cope is fastened. The usual form is a large circular clasp made of gold or silver and enriched, with jewels. A 14th-century "morse" ornamented with translucent enamel is in the British Museum. The word comes through the O. Fr. mors, from the Lat. morsus, the catch of a buckle, from mordere, to bite.

MORSHANSK, a town of Russia, in the government of Tambov, 50 m. N. of the city of Tambov, on the Tana river. Pop. (1900), 25,913. The village of Morsha was founded in the middle of

Five years later the captain of the ship identified under oath Morse's completed instrument with that which Morse had explained on board the "Sully" in 1832.
the 17th century, and received municipal institutions in 1770; but within a very few years it became a wealthy town, owing to its situation in a very fertile district. Since it was brought into railway communication with Ryazshk (81 m. west of the railway between Moscow and Ryazan) it has become the chief centre for the trade in wheat raised in the governments of Tambof, Penza, Saratov and in the eastern districts of the government of Ryazan. There are also extensive dealings in flour, hemp-seed, tallow and potash.

**Mortagne,** a town of northern France, capital of an arrondissement in the department of Orne, 24 m. E.N.E. of Alençon by rail. Pop. (1906), 3583. A vaulted entrance (15th century), relic of an old stronghold, and the church of Notre-Dame (15th and 16th centuries) with a fine northern portal are of interest. The town is the seat of a sub-prefecture and of a tribunal of first instance, and is a celebrated market for horses of the Perche breed. Mortagne, once capital of the Perche, dates from the 10th century.

**Mortain,** a small town in the department of La Manche, France, the chief town of an arrondissement and seat of a sub-prefecture. It is beautifully situated on a rocky hill rising above the gorge of the Cance, a tributary of the Seine. Mortain is a parish church without a tower, a fine example of the transition style of the early 13th century, with a massive tower of the 14th and a Norman doorway dating from the original collegiate church (1058). Close to the town is the Abbaye-Blanche, founded as a Benedictine convent in 1105 and soon afterwards affiliated to Citeaux. The church is a perfect example of a Cistercian monastic church of the late 12th century, and portions of the 12th-century cloisters also survive. The population is between 2000 and 3000.

Mortain was, in the middle ages, the head of an important comté, reserved for the reigning house of Normandy. In or about 1049 Duke William took it from his cousin William, "the warling," and bestowed it on his half-brother, Robert, thenceforth known as "count of Mortain," whose vast possessions in England after the Conquest (1066) gave name to "the small fees of Mortain," which owed less (knight) service to others. Robert was succeeded as count by his son William, who rebelled against Henry I., was captured at the battle of Tinchebrai (1106) and forfeited his possessions. Some years later, Henry II. restored them to his brother Stephen, who became count in 1135. On Stephen's death (1154) his surviving son William became count of Mortain, but when he died childless in 1159 the comté was resumed by Henry II. On the accession of Richard I. (1189) he granted it to his brother John, who was thenceforth known as count of Mortain till he ascended the throne (1199). With his loss of Normandy the comté was lost, but after the capture of the province by the House of Lancaster, Edmund Beaufort, a grandson of John of Gaunt, was created count of Mortain and so styled till 1441, when he was made earl of Dorset.

As the counts are often described as "earls" of Mortain (or even of "Moreton") the title is sometimes mistaken for an English one. It has also, through erroneous spelling, been sometimes wrongly derived from Mortagne-en-Perche. (J. H. R.)

**Mortar,** the name (1) of a vessel in which any material may be crushed or pounded, and (2) given to various compositions used in building and consisting of lime and cement with sand or other fine aggregate, well mixed by manual labour or machinery with a proper quantity of clean water (see below, and also Brickwork). The Latin name both for such a vessel and for the material as mixed in it is *mortarium.* The earlier English form *mortar,* from Fr. *mortier,* has been in modern English more closely adapted to the spelling of the Latin original. As applied to a vessel, the name is chiefly used for one employed in the preparation of drugs, which are ground or triturated in the "mortar" by means of a pestle (Lat. *pistillum; pinsera,* to pound). The name has also been given, from a resemblance in shape to the vessel, to a short thick piece of ordnance, resting on a "bed" formerly used for high-angle fire. The barrel was always very short, normally even shorter than it was wide, and sometimes even resembled a bowl in shape. The place of the mortar in artillery is now taken by the howitzer. In modern times the name "mortar" is occasionally used for a particularly short howitzer. (See Ordnance.)

**Building Mortar.**—The sand从容 aggregate forming the mortar and placed into a form within which lime in the requisite proportion has been turned over and well worked with water, is then used for building. In this case, unless the materials are thoroughly incorporated, it should rather be kept covered with sacks until well tempered. For large works a mortar mill working by hand, steam, or other power effects a considerable saving in fuel, and bricks or lime, if exposed to weather, and fire clinkers may take the place of sand when the mill is employed, as the action of grinding reduces any large pieces to small sandlike particles.

The remarks above apply to ordinary lime mortar. Mortar of hydraulic lime, cement mortar, or mortar gauged with cement, must be mixed up in quantities sufficient only for immediate use. Any material not used at the time, or at least the same day, will be wasted; cement cannot be reworked after it has begun to set as its setting properties are destroyed.

Slaking is a most important part in the process of making mortar. There are three methods of slaking lump lime—the first by immersion, the second by sprinkling with water, and the third by exposure to the air. In the first, the lime absorbs moisture. Different qualities of lime require varying amounts of water, but the average quantity is about a gallon and a half to every bushel of lime. It should be added at one time and the mortar stirred or lightly beaten. When the lime is slaked, the water is used for mixing mortar. These are unsuitable for plastering unless slaked for a long period. It will at once be seen that when mortars composed of these limes are used immediately after mixing, slaking must continue for a long time, drying up the moisture necessary for setting the mortar to crust and to rub in the joints of the brickwork. This fact gives us the reason for the old Roman enactment which set forth that lime should be slaked for three years before using. In the south of France (at Limoges) lime is said to be slaked for 20 years.

The practical application of mortar to building work, and the methods of pointing the joints of brickwork and stonework, are described and fully illustrated in the article on Brickwork.

The results may now be measured, and it is shown to be certain that the hardening of mortar is due to several causes acting collectively. With ordinary lime mortars the chief causes of hardening are the absorption of carbonic acid from the air and the combination of part of the water with the lime. Mortars are frequently composed of a silicate of which the setting is composed forms silicate of lime. The initial setting is due to the evaporation of the excess of water and to the production of minute crystals of hydrate of lime which slowly absorbs carbonic acid gas from the air. With mortars of rich lime, the lime is dried up before it is exposed to the air, or it is covered with a water proofing by the use of a surface which prevents ready access of air to the interior and retards setting. In illustration of this peculiar property of lime to remain soft, some remarkable cases may be mentioned. One of the bastions erected by Vauban in gas was left by the constructionist, in 1822, a hundred and fifty six years after erection. The lime in the interior of the masonry, where it was inaccessible to the action of the atmosphere, was found to be quite soft. Dr. John of Berlin mentions that in 1714 he assumed that the presence of magnesia in mortar was easily removable, the mortar being in a state of pulp. The brickwork, built with Roman cement, was found to be quite hard.

The Romans were convinced that it was owing to prolonged and varied use that the lime slaked and used for building hardened and were not defaced by cracks. L. B. Alberti mentions in his writings that he once discovered in an old trough some lime which had been left there five hundred years and that it was quite soft and fit for use.

The setting and hardening of hydraulic limes and cements are due primarily to the carbonation of lime, which absorbs carbonic acid from the atmosphere, and not by mere absorption of carbonic acid gas from the atmosphere. As a consequence we find that this variety of limes and cements has the valuable property of setting hard while it is in water and in many cases growing increasingly hard with the lapse of time.

Opinions differ very widely on the question of the suitability for building purposes of limes or cements which contain an appreciable quantity of magnesia. Some magnesia in an ordinary cement that the expansion which often occurs in floors and other works of concrete from one to four years after laying may be justly attributed to the presence of this substance. For mortars, however, the use of magnesia is not detrimental to the value of the matrix, but on the contrary may be a source of strength, for experiments show that it reduces the energy of
slewing and increases that of the setting processes. Cements containing magnesia are pronounced both by Whitman and Chatney to resist the dissolving action of sea-water better than those in which no magnesia is present, and it is pretty well established by experience that cements derived from argillo-magnesian limestones furnish a durable cement for construction in the sea.

The old mortar of the Romans, which proves its great property of endurance by many of their works still remaining, was in all probability composed of lime mixed with pozzolana or 'tuss.' These materials are similar in character and obtained from extinct volcanoes—in the case of the Romans from the Italian volcanoes, but also from extinct volcanoes in the valleys of the Rhine and in Holland. Good as these mortars undoubtedly were, it may be safely asserted that no cement or mortar has been discovered to excel in strength, or in durability in all climates, the Portland cement of the present day. The best varieties of this material are made in England, the country of its origin, much of the continental and American products being defective in the quality which combines to make a good cement. (For the properties of Portland cement and the method of its manufacture see CEMENT.)

The comparative strengths under tensile stress of grey-lime mortar, Portland-cement mortar, and the addition of lime, are given in the following table, which is the result of a series of tests by G. R. Redgrave.

It is a good plan, where the question of cost precludes the use of mortar made entirely of cement, to add to lime mortar mixed in the usual proportions a small quantity of Portland cement. This is termed "gauged" lime mortar. By this addition the strength is greatly increased, and the extra cost is but slight.

The following table shows the force required to tear apart common stock bricks bedded in mortar, mixed in proportions commonly used, and left to set and harden for four weeks.

These results show clearly that the adhesive strength of mortar varies according to the proportion of sand used, the power of resistance of the mortar to the force brought to bear upon it decreasing as the sand is increased.

The primary cause of the premature decay which sometimes takes place in mortars and like material is due to the presence of mud and decayed vegetable and animal matter in the sand. Mortars should be kept free from such dangerous ingredients during the processes of proportioning.

The effect of salt in mortars as a preventive of the destructive effects of frost has not as yet been thoroughly determined, and the few experiments that have been carried out show varying results. German experiments, cubes of stone were joined together with cement mixed with water of different character. Ranges from pure rain-water to water containing from 2 to 8% of salt. Before the cement was dry, air at a temperature varying from 80°F. to freezing-point, after which they were kept for seven days in a warm room. The samples were then examined with these results: The cement mixed with pure water was quite crumbled, having its threads divided into smaller pieces, but while containing 2% of salt was in rather better condition, while that containing 8% of salt had not suffered from its exposure to frost. The use of salt causes much efflorescence on the face of the work, and should therefore be used with caution. In this case, it would be undesirable, nor should salt be employed for work of that sort to be subsequently painted. The mortar for the brick facing of the Forth Bridge below water was composed of one part of Portland cement and one part of sand mixed with salt water in a mill. Briquettes made from this cement with it is a terrible stress of an average of 365 lb per square inch when a week old, and of 510 lb at five weeks after mixing. Salt has no effect upon the strength of a mortar, although it retards the setting process somewhat.

Cement mixed with a percentage of sugar (usually 2% and under) has been used with varying success. In India sugar is a frequent ingredient in mortar, probably because it has the effect of preventing too rapid setting; it also retards the drying of the material. The sugar must be dissolved in the water used for gauging, as the results obtained when the sugar is mixed with the dried cement in the state are not good. The addition of sugar to water enables it to take up about fourteen times more lime than pure water. It is supposed by many writers who have studied the methods of the ancients that old Roman mortars contained strong ale, wort or other saccharine matter, and it is probable that the use of sugar with lime passed from India to Egypt and Rome. The following is an extract from the "Roodee Treatise on Engineering," a work of reference published in India: "It is common in this country to mix a small quantity of the coarsest sugar, 'goor' or 'jagher,' as it is termed, with the water used for mixing up mortars. Experiments were made with bricks joined together by mortar consisting of one part of common shell lime to one and a half parts of sand, one pound of 'Jagher' being mixed with each gallon of water. The bricks were set in water up to the level of the broken mortar, the breaking weight of the joints in twenty trials was 6 3/4 lb per square inch. In twenty-one specimens joined with the same mortar without the 'jagher' the breaking weight was 4 1/2 lb per square inch.

Of the saccharine matters used in mortar, treacle seems to give the best results, rough cane sugar being next in effectiveness; beetroot sugar is not a good material to use.

The By-Laws made by the County Council in 1891 under sec. 16 of the Metropolis Management and Buildings Act Amendment Act 1875 require that "the mortar to be used in the construction of walls must be composed of freshly burned lime and clean, sharp sand or grit without earthy matter, in the proportions of one of lime to three of sand or grit." The cement to be used must be Portland cement or other cement of equal quality to be approved by the district surveyor, mixed with clean, sharp sand or grit in proportions of one of cement to four of sand or grit. Burnt ballast or broken brick may be substituted for sand or grit, provided such material be properly mixed with lime in a mortar mill.

The varieties of lime and cement chiefly used for mortar in the British Isles are the following:

**Pure and fat limes should not be used for mortar.**

Grey stone lime, feebly hydraulic, makes a good mortar, but should not be employed for work below ground or in other damp situations. It is chiefly used in the chieftly used in the construction of buildings in Dorset, Mersham. It is used in the proportion of one part to two or three parts of sand.

Blue lias lime is eminently hydraulic and should be used in good class work. Its use is a necessity for foundations and work in damp situations where Portland cement is not employed. It is used in the proportion of one part of lime to four or five parts of sand. The varieties are obtained from Watchet in Somerset, Barrow-on-Soar in Leicestershire, Rugby in Warwickshire, and Lyme Regis in Dorsetshire. A typical lime shows on analysis the following composition:

| Proportions. | 14-80 |
| Silica | Iron oxide and alumina | 8-75 |
| Lime | 77-00 |
| Magnesia | 1-25 |
| Carbon dioxide | 0-90 |
| Water and loss | 2-60 |

| Insoluble matter and loss | 0-72 |

Portland cement is the best matrix known, since it is the most powerful and the most durable. It is used for mortar wherever great strength, hard-wearing properties, and resistance to dampness are required. It should weigh 112 lb per struck bushel and be ground fine enough to pass through a sieve having 2500 meshes to the square inch and leave not more than 10% on the sieve. Test briquettes after setting under water for seven days should stand a tensile strain of 350 lb on a square inch. It is used in the proportions of one part of cement to from one to five parts of sand.
MORTARA, E.—MORTGAGE

American Portland cement was manufactured in 1874 by Mr. David O. Saylor.

The chief works of reference on this subject are G. R. Burnell, *Limes, Cements, Mortars*; Rivington, *Notes on Building Construction*; F. W. Taylor and S. E. Thompson, *A Treatise on Concrete, Plaster and Reinforcement* (J. Bt.).

MORTARA, Edgar, an Italian Jew, of a Bologna family, whose abduction in early childhood (1858) by the Inquisition occupied for several years the attention of European diplomacy. Edgar Mortara, when between five and six years of age, fell ill.

His nurse, a Catholic, arranged with her priest for his baptism in that faith, unknown to his parents, on the 24th of June 1858. She had acted in the same way with his elder brother, who had been ill a year or two previously, but on his recovery the boy continued to be educated as a Jew. This time she determined to make sure of her convert. Everything was concerted in advance with the ecclesiastical authorities, and immediately after the baptism both child and nurse disappeared. The story became public property, and protest was aroused in nearly every European country. The English and French governments made representations to the Vatican, but Plus IX., through the medium of the *Civiltà Cattolica*, maintained that the question at issue was a spiritual one, outside his temporal jurisdiction. He accordingly declined to take any action, meanwhile indicating the direction of his sympathies by making Mortara his ward. In 1866 the Pope's family induced the Italian government to arrange the prosecution of the nurse. The facts revealed that she had entered a nunnery, and subsequently, on the threat of intervention by Prussia, induced the Mortara family to withdraw their plaint. After the capture of Rome by the Italian troops in 1870 Edgar Mortara had the opportunity of reverting to Judaism, but he refused to do so, and not long afterwards became an Augustinian.

MORTARA, a town of Lombardy, Italy, in the province of Pavia, 354 ft. above sea-level, a railway junction situated between the Ticino and the Po, 32 m. by rail S.W. of Milan. Pop. (1901), 7298 (town); 8607 (commune). Lines run to Milan, Pavia, Alessandria, Casale Monferrato and Vercelli. The church of San Lorenzo is in the Gothic style of the 14th century with a brick façade. Outside the town is the Lombard Romanesque church of S. Albino. Mortara has iron-works and manufactures of hats and cheese.

Here the Austrians defeated the Piedmontese in 1840.

MORTGAGE (an old French legal word, meaning "dead pledge, translated in medieval Latin mortuum vadium"); the securing "money of money's worth" by making it a charge upon property, real or personal, so that if the debt be not paid by a time agreed upon by the parties, the creditor may foreclose or sell the property and pay himself out of the proceeds. In English law this is done by an actual or executory conveyance of the property to the creditor, subject only to its being defeated if the debt should be paid at the time fixed—an arrangement to which the law has attached peculiar incidents designed to carry out its real object.

The history of mortgage transactions in Roman law shows three well-marked stages. In the beginning the estate was conveyed absolutely to the creditor, who made a covenant (fodicia) to recover it when the debt should be paid. All the interest, however, in the meantime passed from the debtor to the creditor, and should the latter refuse to recover there was no remedy to the original owner except a personal action. In the second stage (that of pignus) the property did not pass to the creditor; he merely received possession of the thing pledged together with certain rights of sale, in the event of payment not being made at the time appointed. Lastly, without parting with the possession even of the pledge the debtor could create a lien or charge (kyphotheca) over it in favour of the creditor, who acquired thereby a right on failure of payment to follow the thing by real action against the possessor, whoever he might be, and to repay himself from the proceeds of his sale.

The mortgage of English law is the result of two distinct influences. Its origin and form belong to the common law; the restrictions by which it is made to serve the purpose of a security only, and nothing more, belong to the courts of equity. In the eye of the common law the mortgagee was the owner of the estate conveyed in the mortgage; in equity the mortgagor remains the real owner, and the mortgagee is merely an encumbrancer. A, the owner of land in freehold, conveys to B and his heirs, with a proviso that on repayment of money lent by B to A, on a future day, with interest until payment, B or his heirs will reconvey the estate to A and his heirs, and that, until default be made in payment, A and his heirs may hold without interruption from B and his heirs. This is a common mortgage of land, and at law, after failure of payment, the land belonged absolutely to the mortgagee, while in the meantime, before payment, the legal estate was considered to be vested in him, subject only to being defeated by payment at the proper time. The court of chancery first interfered in the reign of James I. to decree a redemption after forfeiture, and a case in the reign of Charles I. decided that payment after forfeiture was the same as payment before. The right of the mortgagor to redeem his estate after it has been forfeited, according to the terms of the deed, is called his equity of redemption. No agreement between the parties was suffered to oust the jurisdiction of the court, or to deprive the debtor of his equity of redemption. And this equity, at first regarded as a mere right of the debtor, became established in course of time as an estate in land which descended to the heirs of the mortgagor. On the other hand, the interest of the mortgagee is part of his personal estate, and passes to his executor and not to his heir. In spite of the terms of the mortgage, the owner of the land is still the owner, and the mortgagee is a creditor for the money he advanced and the interest thereon. It may be a question whether a given deed is a conveyance or a mortgage, and the court, in deciding, will look at all the circumstances of the case, and will treat it as a mortgage when it was the real intention of the parties that it should operate as a security only. Thus, if the price was grossly inadequate, if the purchaser was not legally imployed, or if he was not instructed for the money to the grantor, retaining an amount equivalent to interest, if the expense of the deed was borne by the grantor, there would be reason to believe that the conveyance was only meant to be a mortgage. And "once a mortgage, always a mortgage"; no subsequent agreements can change its character.

A mortgagee may, however, on default of payment file a bill of foreclosure requiring the mortgagor to pay the amount of the debt with interests or costs by an appointed day, or submit to be deprived of his equity of redemption. The effect of failure to pay by the time appointed would be to make the mortgagee absolute owner of the estate; but the court in any foreclosure suit may, at the request of either side, order a sale instead of a foreclosure. And a power of sale is now implied as one of the incidents of the mortgage, unless forbidden or varied by express destination. The mortgagee is entitled to retain out of the proceeds of the sale the amount of his principal, interest and costs, the surplus belonging to the mortgagor. A mortgagor cannot require the creditor to receive payment at the time appointed or the deed; and, on default of payment at the appointed time, he must give the creditor six months' notice of his intention to pay off the mortgage, so that the creditor may have time "to look out for a fresh security for his money."

When the same land is successively mortgaged to different persons, their rights take priority according to their chronological order. But the operation of equitable doctrines in the formation of the law of mortgage leads to an important modification of this rule. Of the successive mortgagees, the first only takes the legal estate, and this, according to the maxim...
of the court of chancery, will turn the scale when there is an
equality of equitable rights between two contracting parties.
Thus, if the third mortgagor had no notice at the time of making
his advance of the existence of the second mortgagee, the
equities of the two claimants are supposed to be equal, and if
nothing else intervened priority of time would decide the order
of their rights. But if the third mortgagee gets an assignment
of the first mortgage, he can tack his third mortgage to the first,
and so postpone the second mortgagee. And if the first mort-
gagee himself makes an additional advance after the date of
the second mortgage, but without notice of it, his whole debt
will take precedence of the second mortgage. A similar result
of equitable rules is seen in the consolidation of securities. Two
separate estates, mortgaged at different times and for different
sums of money by the same mortgagor to the same mortgagee,
are regarded as consolidated, so that the whole of the land
becomes security for the whole of the money, and the owner
cannot redeem either mortgage without redeeming the other.
If the mortgagee should have mortgaged another estate for
more than its value, the holder of the deficient security may
buy in the first mortgage, consolidate it with his own, and
exclude the second mortgagee.
An equitable mortgage is constituted simply by the deposit
of title-deeds in security for money advanced. The enactment
of the Statute of Frauds that no action shall be brought on
"any contract or sale of lands," &c., or any interests in or
concerning them unless the agreement be in writing and signed
by the party to be charged, has been cited as incompatible
with the recognition of equitable mortgages, but it is argued
by Lord Abinger that the act was never meant to affect such
a transaction. The deeds which are the evidence of title could
not be recovered in an action at law, and, if they were claimed
in equity, the court would require the claimant to do equity
by repaying the money borrowed on the deposit. Any sub-
sequent legal mortgagee, having notice of the deposit, will be
postponed to the equitable mortgagee, and when the legal
mortgagee has not inquired as to the title-deeds the court
will impute to him such knowledge as he would have acquired
if he had made inquiry. A Welsh mortgage is one in which
an estate is conveyed to a creditor, who takes the rents and
profits in lieu of interest and without account, the estate being
redeemable at any time on payment of the principal. Any
form of property, with few exceptions, may be mortgaged.
United States.—In the United States there has been express
legislation dealing with mortgages of land in most of the states.
For the most part legislation has followed the lines of the English
law, but there is a great variation in the extent to which the
principles of equity have been substituted for the rules of
common law. In some states, the mortgagee deed is held to
create a seisin of and an estate in the premises, with all its
common law incidents, to be enforced if need be by ejectment.
In others, the mortgagee’s rights are limited to such as the rules
of equity prescribe, and may not be enforced by a suit at law.
In New York, if the interest is not deemed an estate
at all, but is here only to be enforced by the sale of the premises
as a means of paying the debt.

Mortgages; L. A. Jones, Treatise on the Law of Corporate Bonds and
Mortgages (Indianapolis, 1897).

MORTIER, EDOUARD ABDOLPH CASIMIR JOSEPH, DUKE
of Trevise (1768–1835), marshal of France, was born at Cateau
Cambrésis on the 15th of February 1768, and entered the army
as a sub-lieutenant in 1791. He served in the campaigns of
1792 and 1793 on the north-eastern frontier and in the Nether-
lands, and subsequently on the Meuse and the Rhine. In
the war against the second coalition in 1799 he was promoted
successively general of brigade and general of division. His
conduct of the French occupation of Hanover led Napoleon
to include Mortier in the first list of marshals created in 1804.
He commanded a corps of the Grande Armée in the Ulm campaign
in which he distinguished himself particularly by his brilliant
action of Dürenstein; in 1806 he was again in Hanover and
north-western Germany, and in 1807 he served with the Grande
Armée in the Friejland campaign. In 1808 he was created
duke of Treviso, and shortly afterwards he commanded an army
corps in Napoleon’s campaign for the recapture of Madrid.
He remained in Spain for two campaigns, winning the victory
of Ocaña in November 1809. In 1812 and 1813 he commanded
the Young Guard, and in the “defensive” campaign of 1814
he rendered brilliant services in command of rearguards and
covering detachments. In 1815, after the flight of Louis XVIII,
he rejoined Napoleon and was given a high command, but at
the opening of the Waterloo campaign he fell ill. After the
second restoration he was for a time in disgrace, but in 1819
he was readmitted to the Chamber of Peers and in 1825 received
the Order of the Saint Esprit. In 1830–1831 he was ambassador
of France at St Petersburg, and in 1834–1835 minister of war
and president of the council of ministers. In 1835, while
accompanying Louis Philippe to a review, the marshal with
eleven other persons was killed by the bomb aimed at the king
by Fieschi (July 28, 1835).

MORTIFICATION, a term used in pathology and surgery,
signifying a local death (Lat. morte) in the animal body. A
portion of the body may die in consequence of the disturbance
of its nutrition by inflammation, or of a cutting off of the blood-
supply, as by pressure upon, or injury to, the blood-vessels.
A comparatively slight injury affecting a portion of the body
imperfectly supplied with blood may give rise to an inflam-
matory condition which in a healthy part might pass unnoticed,
but which, in consequence of imperfect nutrition, may end in
mortification. If the flow of arterial blood only is arrested, the
part depending upon it for nutrition becomes numb, cold and
shrivelled, and the form of mortification known as dry gangrene
occurs. This is apt to be met with in oldish persons with
diseased vessels and feeble heart-action, especially if the blood
is rendered less nutritious by the presence of diabetes or
kidney disease. The rule of treatment in all cases of threatened
mortification is to keep the part warm by flannel or cotton-wool,
but to avoid all methods which unduly hurry the returning
circulation. Such increase would give rise to excessive reaction,
which, in tissues already weakened, might actually produce
mortification. When the part is dead it should be wrapped
up in dry antiseptic dressings to prevent putrefaction.
The surgeon should then wait until the “line of demarcation,”
a linear ulceration, between the living and the dead part is evident,
and then, if the case permits, should amputate at a higher level.
In spreading gangrene, in which acute sepsis is present, and
in which no line of demarcation forms, the best chance for
the patient is promptly to amputate high up in sound tissues.
In these cases the blood is generally poisoned, and if the patient
recovers from the primary shock of the operation, the disease
may reappear in the stump, and lead to a fatal result.

Frost-bite.—Under the influence of cold, the blood-vessels
contract, and less blood is conveyed to the tissues. Frost-bite
is particularly apt to attack the feet, the hands, and the tips
of the ears. The yellow spot is unassociated with pain, for the
reason that the nerves are numbed. As no blood is passing
into the skin, the parts look tallow, and thus attract
the attention of the companions of the frost-bitten man, who perhaps
has no thought of there being anything amiss. But because
the tissues are frost-bitten it does not follow that they will
not recover. The great danger is that, as the blood in the
vessels becomes thawed, there will be so much reactionary
flow through the tissues that acute inflammation will follow.
And this inflammation of the damaged tissues is very likely
to cause mortification. The re-establishment of the circulation,
therefore, should be undertaken with the greatest possible care.
The frost-bitten individual must not be brought near a fire nor
even into a warm room. Nothing warm should come in contact
with the affected parts. The best thing to do is to rub them
with snow or with cold water. The thawing is associated with
much pain, and in the case of the hand or foot this may be
diminished by raising the part, so as to help the return of the
venous blood to the heart. If mortification follows, the parts
occupied himself with local feuds, but seized the royal castle of Bridgnorth. So great was his power in the marches, that he alone, deserted by the earl of Hereford, armed and held his three castles against Henry II. Although forced at last to submit, he was allowed to keep Wigmore and the ruins of Cleobury. This proud baron died at Cleobury (c. 1181) in the habit of a canon of the abbey which he had founded at Wigmore.

Ralph de Mortimer, the 5th baron of Wigmore (d. 1246), married Gwladys the Swart, daughter of Llewelyn the Great, prince of Wales, and by her was father of Roger, whose bride, Maude de Breuse, daughter and co-heir of that William de Breuse whom Llewelyn had hanged, brought in a third of the honour of Breuse of Brecknock, and a share of the honour of the earl's marshal. So came the lordship of Radnor with other lands, and, as Eyton justly remarks, the history of the Mortimers ceases to be a provincial record. The last-named Roger stood steadfast for the Crown during Henry III.'s struggle with his barons. He found the fleet horse that carried Edward from his captivity. He led the rear-guard at Evesham, where his marchers hacked the head from earl Simon, and sent it to their lieger, his friend the king. "After the victory," says Eyton, "no privilege, reward or honor was too great to ask." Dying in 1282, he was succeeded by Edmund, the eldest surviving son (d. 1304), Roger, a third son, founding the line of Mortimer of Chirk.

By Margaret de Fienes, a kinswoman of Queen Eleanor of Castile, Edmund Mortimer had, with other issue, a son and heir, Roger (b. 1287), whose great inheritance was increased on his marriage with Joan, daughter and heir of Peter de Genevile, her grandmother being a co-heir of Lucy. The whole of the Genevile lands, with the half of the Lacy fee in England and Ireland, came through her to the Mortimers, who now added the castle town of Ludlow and half Meath to their estates. As the king's lieutenant in Ireland during Edward Bruce's invasion of 1316, Roger Mortimer defeated the Lacy's, his wife's jealous kinsfolk, and made her inheritance secure. With the aid of his uncle Roger Mortimer of Chirk, he assured the Mortimer power on the Welsh marches. During the war with the Despensers, the force of the Mortimers was cast against the king's enemies. But, after Mortimer Castle had been taken and Roger, uncle and nephew submitted and suffered a harsh captivity for two years in the Tower of London. The uncle died in his prison, whence the nephew made a famous escape to France. At the court of Charles IV. the exile met Isabelle, the queen of England, and early in 1326 the scandal of her close friendship with the lord of Wigmore had reached England. When the queen and her mercenaries from Germany and Hainaut landed at an English port in September, Mortimer was with her, and he followed the flight of the king to Wales. He was among the judges of the elder Despenser at Bristol, and of the younger, his chief enemy, at Hereford. After the parliament had deposed Edward II. and made the young Edward king in his stead, Roger, as the queen's paramour, ruled England. Enriched by the lands of the Despensers, and by those of the earl of Arundel, beheaded at his command, Mortimer, who was created earl of March in 1328, never ceased to add greedily to his possessions and offices. When he held a Round Table, he summoned to it, with the young king and the queen-mother, almost all the nobles of the kingdom, and was, says Robert of Avesbury, "as it were, king over them all." But his fate followed suddenly upon these doings. Lancaster turned in vain upon the aggrieved march-lord, but the young king, impatient of his own puppet-like place in Mortimer's policy, worked secretly and surely for his fall. Montague's men-at-arms entered Nottingham Castle by night, and joining the king, seized the favourite in his chamber next the queen. Mortimer, with the courage of his race, turned to bay and struck dead a knight who was the king's steward. But he was hurried to London and condemned by the peers; his death followed suddenly. Like any foot-pad, he was drawn at the horse-tail to the elms of Tyburn, where his body hung two days upon the common gallows.
MORTISE—MORTON, EARL OF

The earl's son and heir, Edmund Mortimer, had been married to Elizabeth of Badlesmere, heir of her brother Giles. He died eight years after his father's fall, and his young son Roger, as he grew up, was trained to inherit the family estates. This Roger fought at Crécy in "the king's battle." A founder of the Order of the Garter, he was summoned as a baron and obtained a reversal of his grandfather's attainder. In 1355 he was summoned as earl of March. On the death of his grandmother, Ludlow Castle became the chief seat of his house. But following his king in the invasion of Burgundy, he died suddenly at Rouvray in 1360. His wife, a grand-daughter of that William Montague, earl of Salisbury, who had captured his grandfather at Nottingham, survived him two-and-twenty years.

His only son, Edmund, a boy nine years old, succeeded him as 3rd earl of March (1351–1358). A bride was found for him in the royal house. His marriage with Philippa, daughter of Lionel of Antwerp, duke of Clarence, by Elizabeth de Burgh, the heiress of Ulster, added the earldom of Ulster to his style, and brought his issue into the direct succession of the Crown. Like many of his race, he died young, of a chill caught in fording a Munster river on a winter's day, and his countess was dead before him. Elizabeth, their eldest child, became the wife of the future Edward the Black Prince, protector of Portugal, and Roger, who succeeded to his father's two earldoms as a boy of seven, and was at once appointed lieutenant of Ireland. His marriage was given to the earl of Kent, who married him to his daughter, Eleanor Holand, the niece of King Richard. In the parliament of 1385 the king named him as heir-presumptive to the throne. The Panegyrist of his family are loud in their praise of his knightly doings and his great beauty, but they speak also of his lion-like ferocity, of his lasciviousness, and of his neglect of divine things. When in Ireland he defied the statute of Kilkenny, and ordered his armour and horse-harness before the fashion of an Irish chieftain. He wore the Irish mantle on the day in 1398 when, in one of his petty wars with the Leinster men, he was struck down at Kells as he charged far before his horsemen. The body, mangled by Irish skenes and axes, was brought home to be laid by his fathers in their abbey of Wigmore.

Once more a child succeeded to the earldoms. Edmund, 4th earl of March, was six years old at his father's death, and was, for the king's party, heir-presumptive to the throne. He was changed by the coming to power of the Lancastrian party, and Henry IV.'s first parliament recognized Henry's son as heir-apparent. Although Edmund and his brother Roger were brought up honourably with the new king's younger children, they were in strict custody until the king's death, broken only by the attempt of their uncle, Sir Edmund Mortimer, and his father-in-law, Owen Glyndwr, to carry them off from Windsor to Wales, where the young earl would have been proclaimed king. Henry V., however, released the earl and restored his lands, and absolved March from any share in the plot of the earl of Cambridge, who had married Anne, sister of the earl. March served the king in his French wars, although a dyersey caught in the camp at Harfleur seems to have kept him from his share in the glory of Agincourt. On the accession of Henry VI. the earl was appointed to the lieutenancy of Ireland which had been held by his father and grandfather, and in Ireland, on the 19th of January 1425, he died suddenly of the plague. His wife, Anne, daughter of Edmund, earl of Stafford, had borne him no child, and thus, his brother being dead before him, the illustrious house of the Mortimers, earls of March and Ulster, became extinct. Their lands and earldoms passed to Richard, duke of York, son of Richard of Cambridge, by the last earl's sister, and the great name of Mortimer disappeared from the English baronetage.

MORTISE, or MORTICE (adapted from the Fr. mortaise; cf. Ital. mortise and Spanish mortaja; the origin is unknown; Celtic equivalents, such as Gaelic mortais, are of French origin), a term for a socket or cavity cut in a piece of wood, or other material, into which a corresponding projecting end, a "tenon," fits, the two when fitted together forming a "mortise-joint," for fastening two beams or other pieces of timber together.

MORTLAKE, a village in the Kingston parliamentary division of Surrey, England, on the Thames, 63 m. W. of London. Pop. of parish, which includes East Sheen (1901), 7774. It has been associated with the Oxford and Cambridge boat-race since 1845, the race finishing here. The village appears in Domesday, and the manor belonged to the Archbishops of Canterbury until the time of Henry VIII., when it passed by exchange to the Crown. From the early part of the 17th century until after the civil wars Mortlake was celebrated for a manufacture of tapestry.

MORTMAIN (O. Fr. mortmain; med. Lat. mortua manus, dead hand), the state or condition of lands or tenements when held by a corporation in perpetual or inalienable tenure. Alienation in mortmain having the effect of depriving the lord of the incidents of seigniory, which arose through the death or felony of the tenant or failure of his heirs, many English statutes ordere mortmain. The earliest is that of Henry III. 36 (Magna Carta); others before Edward I. 3 and 4 (De Viris Religiosis); 13 Edward I. 32; 15 Richard II. 5; and 23 Henry VIII. 10. The present law is regulated by the Mortmain and Charitable Uses Act 1888, as amended by the act of 1891.

MORTON, JAMES DOUGLAS, 4TH EARL OF (c. 1525–1581), Scottish statesman, was the second son of Sir George Douglas of Pittendrigh. Before 1543 he married Elizabeth (d. 1574), daughter of James Douglas, 3rd earl of Morton, a grandson of James Douglas (d. c. 1500), who was created earl of Morton in 1458. The 3rd earl's wife was Catherine, an illegitimate daughter of James IV. In 1553 James Douglas succeeded to the title and estates of his father-in-law, and in 1563 he became lord high chancellor of Scotland. Though his sympathies were with the reformers, he took no part in the combination of Protestant barons in 1565, but he headed the armed force which took possession of Holyrood palace in March 1566 to effect the assassination of Rizzio, and it was to his house that the leading conspirators adjourned while a messenger was sent to Lothian for 5 Richard II. to sign a treaty of security. The queen, before complying with the requirement of the Dunbars, Morton and the other leaders fled to England. Having been pardoned, Morton returned to Scotland early in 1567, and with 600 men appeared before Borthwick Castle, where the queen after her marriage with Bothwell had taken refuge. He was present at the remarkable conference at Carberry Hill, and he also took an active part in obtaining the consent of the queen at Lochleven to an abdication. He led the army which defeated the queen's forces at Langside in 1568, and he was the most valued counsellor of the earl of Murray during the latter's brief term of office as regent. On the death of the earl of Mar (Oct. 28, 1572), Morton, who had been the most powerful noble during this regency, and also during that of the earl of Lennox, at last reached the object of his ambition by being elected regent. In many respects Morton was an energetic and capable ruler. He effected at Perth, in February 1573, with the aid of Elizabeth's envoy, a pacification with Huntly, the Hamiltons, and the Catholic nobles who supported Mary. Only the castle of Edinburgh held out, and this, aided by English artillery, he succeeded in taking in the summer of 1575. The Grandee of Grange and Maitland of Lethington.

The ensuing execution of these men, the bravest and the ablest Scotsman of that age, put an end to the last chance of Mary's restoration by native support. While all seemed to favour Morton, there were under-currents which combined to procure his fall. The Presbyterian clergy were alienated by his leaning to Episcopacy, and all parties in the divided Church by his seizure of its estates. Andrew Melville, who had succeeded to the leadership of Knox, was more decided than Knox against any departure from the Presbyterian model, and refused to be
won by a place in his household. The powerful earl of Argyll and Atholl, a Stuart and Roman Catholic, united with Alexander Erskine, governor of Stirling, who now had the custody of the young king, and others in a league which received such support that they took the field to enforce their will. He surrendered the castle of Edinburgh, the palace of Holyrood, and the royal treasures, retiring to Locheleon, where he busied himself in laying out gardens. But his ambition could not deny itself another stroke for power. Aided by the young earl of Mar, he got possession of Stirling Castle and the person of the king. Civil war was avoided only by the influence of Sir Robert Bowes, the English ambassador. A nominal reconciliation was effected, and a parliament at Stirling introduced a new government. Morton, who secured an indemnity, was president of the council, but Atholl remained a privy councillor in an enlarged council with the representatives of both parties. Shortly afterwards Atholl died of poison, it was said, and suspicion pointed to Morton. His return to power was brief, and the only important event was the prosecution of the two Hamiltons, who still supported Mary and saved their lives by flight to England. The final fall of Morton came from an opposite quarter. In September 1579 Esme Stuart, the king's cousin, came to Scotland from France, gained the favour of James by his courtly manners, and received the lands and earldom of Lennox, the issue of the earl's marriage, probably for the love of his wife. One of his dependants, Captain James Stuart, son of Lord Ochiltree and brother-in-law of Knox, had the daring to accuse Morton at a meeting of the council in Holyrood of complicity in the murder of Darnley, and he was at once committed to custody. Some months later Morton was condemned by an assize for having taken part in that crime, and the verdict was justified by his confession that Bothwell had revealed to him the design, although he denied participation in its execution. He was executed by the maiden—a guillotine that he himself brought from England—on the 2nd of June 1581.

The attainted earldom of Morton passed by charter at his death to a grandson of the 3rd earl, John, 7th Lord Maxwell (1553-1593), who had previously claimed the title. In 1586, however, the attainder was rescinded in favour of Archibald Douglas, 8th earl of Angus (g.v.), a nephew of the 4th earl. Various ears of Morton have now to be distinguished.

Sir William Douglas (d. 1606), who ranks as 6th or 7th earl of Morton, was the 4th earl's near kinsman, being the son of Sir Robert Douglas of Locheleon (d. 1547), and was closely associated with him in his career, the two men being occasionally confused in the histories. He was the custodian at Locheleon Castle of Queen Mary. By the 4th earl he probably married Margaret, daughter of Sir George Douglas of Morton, whose death he attended, and who was the 8th earl's sister. Morton's title, as such, was not extinguished, although not restored. The title of Lord Maxwell was revived in 1586-1592, that of Lord Douglas in 1604-1606, and that of Lord Maxwell of Morton in 1615-1616. All three titles were held by the same family.

In 1581 Morton died, and the title devolved on Robert, 7th Lord Maxwell (1581-1649), known as 7th or 8th earl of Morton, lord high treasurer of Scotland, a zealous Royalist, who on the outbreak of the Great Rebellion provided £100,000 for the cause by selling his Dalkeith estates to the Burrell family; and through John, 8th Lord Maxwell (c. 1586-1613), also claimed the earldom, he was attainted in 1609 and his rights then confined, his titles and estates being restored in 1618 to his brother Robert, with the title of earl of Nithsdale (1620) in lieu. When later Robert Morton mention may be made of James (1702-1768), 14th earl (or, as sometimes numbered, 16th), who became president of the Royal Society (1764), and was distinguished patron of science, and particularly of astronomy. In 1746 he visited France, and was imprisoned in the Bastille, probably as a Jacobite. He was an attainted earl of Morton by his descendant.

MORTON, JOHN (c. 1420-1500), archbishop of Canterbury, cardinal and statesman, belonged to a family which had migrated from Nottinghamshire into Dorset and then to Hampshire, either at Bere Regis or Milborne St Andrew. Educated at the neighbouring Benedictine abbey of Cerne and at Balliol College, Oxford, he graduated in law, and followed that profession in the ecclesiastical courts in London, where he attracted the notice of Archbishop Bourchier. He is said (Dict. Nat. Biog.) to have been "at once admitted to the privy council"; but probably this is a mistake for the ordinary council, of which Morton might well have been made a member when he was appointed master in chancery and chancellor of the duchy of Cornwall. He received a good deal of ecclesiastical preferment from the Lancastrian party, was present, if he did not fight on the losing side, at the battle of Towton in 1461, and was subsequently attainted by the victorious Yorkists. He lived with the exiled court of Margaret of Anjou at Bar until 1470, and took an active part in the diplomacy which led to the coalition of Warwick and Clarence with the Lancastrians and Louis XI., and indirectly to Edward IV.'s expulsion from the throne. Morton landed with Warwick at Dartmouth on the 13th of September 1470, but the battle of Tewkesbury finally shattered the Lancastrian hopes, and Morton made his peace with Edward IV., probably through the mediation of Archbishop Bourchier.

In March 1473 Morton was made master of the rolls, and Edward found employment for his diplomatic talents; he was sent on a mission to Hungary in 1474, and was one of the negotiators of the Treaty of Pecquigny in 1475. In 1479, after receiving a number of minor ecclesiastical promotions, he was elected bishop of Ely. He was one of the executors of Edward IV.'s will in 1483, and the story of the future Richard III., while preparing Morton's arrest, joking with him about the strawberries the bishop grew in his garden at Holborn is well known and apparently authentic. Oxford University in vain petitioned for Morton's release, and after some weeks in the Tower he was entrusted to the duke of Buckingham's charge at Bredon. Here Morton encouraged Buckingham's designs on the Lancastrian earl of Richmond, and in the end joined with the queen dowager, Elizabeth Woodville, and with Henry Tudor, earl of Richmond. He escaped from Bredon Castle to Flanders, avoided Buckingham's fate, and devoted his energies during the next two years to creating a party in England and abroad in the interests of the earl of Richmond.

When Richmond secured the crown as Henry VII., Morton became his principal adviser. He succeeded Bourchier as archbishop of Canterbury in 1486 and Alcock as lord chancellor in 1487; and he was responsible for much of the diplomatic, if not also of the financial, work of the reign, though the ingenious method of extortion popularly known as "Morton's fork" seems really to have been the invention of Richard Fox (q.v.), who succeeded to a large part of Morton's influence. Morton no doubt impressed Lancastrian traditions upon Henry VII., but he cannot be credited with any great originality as a statesman, and Henry's policy was as much Yorkist as Lancastrian. The fact that parliament continued to meet fairly often so long as Morton lived, and was only summoned once by Henry VII. after the archbishop's death, may have some significance; but the probability is that the presence of an able and ambitious statesman, without the security in which he thought he could almost dispense with parliamentary support and supplies. As an ecclesiastic Morton followed orthodox Lancastrian lines: in 1489 he obtained a papal bull enabling him to visit and reform the monasteries, and he proceeded with some vigour against the abuses in the abbey of St Albans. In 1493 he was created a cardinal, and in 1495 was elected chancellor of the university of Oxford. He encouraged learning to the extent of admitting Sir Thomas More into his household, and writing a Latin history of Richard III., which More translated into English. He constructed "Morton's Dyke" across the fens from Wisbech to Peterborough, repaired the episcopal palace at Hatfield and the school of canon law and St Mary's Church at Oxford. He died at Knole on the 12th of October 1500, and was buried in the crypt of Canterbury Cathedral.

MORTON, JOHN MADISON (1785-1880). English playwright, was born at Pangbourne, on the 3rd of January 1811. He was the author of Box and Cox (1847) and a number of other farces. In later life, however, he failed to maintain his success, and eventually became a Charterhouse pensioner, dying on the 10th of December 1891.

His father, Thomas Morton (1742-1838), also a well-known
dramatist, was the author of *Columb or, a World Discovered* (1792); *Speed the Plough* (1798); *The School of Reform, or How to Rule a Husband* (1803); *A Rolande for an Oliver* (1810); and other pieces.

**MORTON, LEVI PARSONS** (1824–1882), American banker and politician, was born at Shoreham, Vermont, on the 16th of May 1824. He was in business at Hanover, New Hampshire, in 1843–1849 and in Boston in 1849–1854. He then became a partner in a New York dry-goods house. He established in 1863 the banking house of L. P. Morton & Company (dissolved 1899), with a London branch which had Sir John Rose (1820–1888) as its principal member. The American firm assisted in funding the national debt at the time of the resumption of specie payments, and the London house were fiscal agents of the United States government in 1873–1884, and as such received the $15,500,000 awarded by the Geneva Arbitration Court in settlement of the “Alabama Claims” against Great Britain. In 1890 Morton became president of the Morton Trust Company in New York City. He was a Republican representative in Congress in 1870–1884, United States minister to Mexico in 1884–1890, and vice-president of the National Bank of Washington during the presidency of Benjamin Harrison in 1889–1893, and in 1895–1896 was governor of New York, signing as such the “Greater New York” bill and the liquor-tax measure known as the “Raines law.” In 1896 he was a candidate for the presidential nomination in the Republican national convention.

**MORTON, OLIVER PERRY** (1824–1877), American political leader, “war governor” of Indiana, was born in Salisbury, Wayne county, Indiana, on the 4th of August 1823. After studying for two years (1843–1845) at Miami University, he practised law at Centerville, Indiana, and in 1852 was judge of the sixth judicial circuit of Indiana. In February 1856 he was a member of the Pittsburg convention which led to the organization of the national Republican party, and in the same year he was a candidate for governor of Indiana; he was defeated, but his campaign resulted in the effective organization of the new party in his state. He was elected lieutenant-governor in 1860, and when Henry S. Lane (1811–1887), then governor, resigned in July 1862 Morton became governor. In 1864 he was re-elected. In meeting all the extraordinary demands resulting from the Civil War he displayed great energy and resourcefulness, and was active in thwarting the schemes of the secessionists in the neighbouring state of Kentucky, and of the Knights of the Golden Circle, the Order of American Knights, and the Sons of Liberty (secret societies of Southern sympathizers and other opponents of the war) in Indiana. In 1863 a hostile legislature sought to deprive him of all control over the militia, and failing in this, adjourned without making the appropriations necessary for carrying on the state government. In this predicament Morton appointed a bureau of finance, and appealed for financial aid to private individuals, bankers, the counties, and even the Federal government. The response was so prompt that he was able to conduct affairs practically single-handed until 1865, when a legislature more favourable to his policies assembled. In 1865, when Morton had a paralytic stroke and went to Europe for treatment, the president entrusted him with a confidential mission to Napoleon III. concerning the withdrawal of the French troops from Mexico. Morton resigned as governor in January 1867 to accept a seat in the United States Senate, in which he served during the rest of his life. He was recognized as one of the leaders of the Radical wing of his party, voting in favour of Johnson’s impeachment, and being especially active on behalf of negro suffrage. In 1870 Grant offered to appoint him minister to Great Britain, but he declined the honour on receiving that a Democrat would succeed him in the Senate.

1 His earliest ancestor in America was George Mourt, or Morton (d. 1624), a merchant of York, England, who seems to have been in London in 1621–1622 as financial agent for the Plymouth colonists. He published *Mourt’s Relation, or Journal of the Beginning and Proceedings of the English Plantation at Plymouth* (1622), apparently written by William Bradford and Edward Winslow, and went to Plymouth, Mass., in the “Anne” in 1623.

He was a candidate for the Republican nomination for the presidency in 1876, and at the national convention of his party received 24 votes for president; the nomination, however, finally went to Rutherford B. Hayes. He died at Indianapolis on the 1st of November 1877.

**MORTON, THOMAS** (1564–1659), English bishop, was born at York, and was educated at York and Halifax grammar-schools and St John’s College, Cambridge, where he became fellow on taking his degree. He was ordained in 1592, and held the office of university lecturer in logic till in 1598 he was presented to the living of Long Marston, Yorkshire. He gained a considerable reputation as a Protestant controversialist, and published numerous works against Roman Catholicism, chief among them being the *Apologia catholica* (1605) and *A Catholike A ppeale* (1609). He held successively the deaneries of Gloucester (1600), Winchester (1600), and a canonry at York (1610). In 1616 he became bishop of Chester, in 1618 bishop of Lichfield and Coventry, and in 1632 bishop of Durham. On the abolition of the episcopate in 1666 he was assigned a pension, which was never paid, and the remainder of his life was passed in retirement.

**MORTON, THOMAS** (c. 1590–1646), usually called Thomas Morton of Merry Mount, English adventurer in America, was a lawyer of Clifford’s Inn, London, and seems to have practised in the west of England. He spent three months in America in 1622; returned in 1625, and settled at Mount Wollaston, in what is now Quincy, Massachusetts; and in 1626, when most of the settlers removed to Virginia, he assumed command of the settlement, and renamed it Merry Mount. 2 Morton, a Royalist rake, soon became a thorn in the flesh of the sober colonists at Plymouth. On May-Day in 1627 his companions erected a May-pole, and, assisted by Indians, indulged in all the revelry and licence then customary in England. “The setting up of this May-pole was a lamentable spectacle to the precise Separatists that lived at New Plimmoth,” says Morton. “They termed it an Idol; yea, they called it the Calf of Horeb, and stood at defiance with the place, . . . threatening to make it a woeful mount and not a merry mount.” In disregard of a royal proclamation, Morton sold bulls and three-armed rackets, not only injuring the trade of Plymouth, but also endangering the safety of the colonists. Morton was therefore arrested and sent to England; and when John Endecott, with a patent from the council for New England, arrived soon afterward he visited Merrymount, which lay within his jurisdiction, rebuked the inhabitants, cut down the May-pole, and renamed the place Mount Dagon. In 1629 Morton returned to America, but was arrested on trivial charges by the Massachusetts authorities, and was confined in the stocks. Later his house was burned and he was sent to England, where he spent a term in the Essex gaol. After his release he wrote his *New English Canaan* (1637), in which he describes the Indians and the natural features of the country, and heaps ridicule upon the New England colonists. In 1643 Morton returned to America. He was imprisoned in Boston in the following year, and was tried before the general court for abusing the colonists. The Privy Council, however, was deceived by his performance; he was convicted of larceny, and started a new career of delinquency, of which he was never disabused. He died in the same year (1646) as that of his release.

2 In his book Morton indulges his fondness for punning and displays of Latinity by calling the place Mare-Mount. (Hill by the sea.)
of the dead. The chief modern use of the word is for a building in which dead bodies awaiting burial may be temporarily kept, for the purpose of inquiry, identification, post-mortem examination, &c. But it has also been applied to many subjects connected with death and burial. In monastic institutions it was the duty of the almoner to send round to other monastic houses notice of the death of a member, asking for prayers for the soul of the dead. This notice was often beautifully illuminated. On being returned with the endorsement of the monastery to which it had been sent, it would be copied into the roll. Both the notice and the roll were known as a mortuaria, or mortuary (see Abbots F. H. Gasquet's English Monastic Life, 1904). In the English Church a "mortuary" was in certain places a customary oblation or offering paid out of the estate of a deceased person to the church to which he belonged. An act of 259 (21 Hen. VIII. c. 6) limited the amount to be paid in mortuaries, the highest being of the value of 10s. in estates above £40. Mortuaries, where customary, can only be enforced in the ecclesiastical courts. The custom has entirely died out, though claims have been made from time to time.

Morvan—Mosaics

Morvan, an elevated region forming the northern continuation of the central plateau of France, and extending over a large part of the department of Nièvre, and over portions of those of Yonne, Côte-d'Or and Saône-et-Loire. Its area is a little over 1000 sq. m. The average elevation is about 1000 ft., the culminating point the Bois-du-Roi, attaining 2095 ft. It is traversed by the Yonne, which has its source on Mt Prénelay (2780 ft.), by the Cure and by several affluents of the Arroux. Geologically it consists chiefly of gneiss and granite. It contains much good pastureage and is abundantly wooded, the exploitation of its forests affording employment to large numbers of the inhabitants.

Morvi, a native state of India, in Kathiawar, within the Gujarat division of Bombay. Area, 822 sq. m.; pop. (1901), 87,406, showing a decrease of 17.2% in the decade, due to famine; estimated revenue, £48,000; tribute, £4000. The chief, whose title is Thakur Sahib, is a Jadeja rajput, of the same clan as the rao of Cutch. The chief products are cotton and grain. The town of Morvi is situated on the river Machhu, 22 m. from the sea and 35 from Rajkot; pop. (1901) 17,820.

Morville, Hugh de, one of the four English knights who perpetrated the murder of Becket. He appears in the service of Henry II. from 1158. His principal estate was at Burgh-on-Sands. After the archbishop's murder Hugh and his associates at first took refuge in Knaresborough Castle; afterwards the king sent them to obtain absolution from the pope. The story runs that all four were enjoined to go on pilgrimage to the Holy Land, but it is not known whether Hugh made his expiation in this way. The date of his death is unknown, but it was in or before 1202/3, when we find his English lands in the hands of his two daughters as co-heiresses.

See Eyton's Itinerary of Henry II.; Ramsay, Angelin England.

Moryson, Fynes (1566-1630), English traveller and writer, was the son of a Lincolnshire gentleman, Thomas Moryson, member of parliament for Grimby. After being educated at Cambridge, where he gained a fellowship at Peterhouse, Fynes Moryson spent many years in travel on the continent of Europe, in Palestine, and in Asia Minor. In 1600 he became secretary to Sir Charles Blount, lord-deputy of Ireland, in which country his brother, Sir Richard Moryson, held an important government appointment. In 1617 Moryson published an account of his travels in Ireland, where he himself witnessed O'Neill's rebellion, in a voluminous work entitled An Itinerary. He died on the 12th of February 1636. The Itinerary was originally intended to consist of five parts; but only three were printed, a fourth being preserved in manuscript in the library of Corpus Christ College, Oxford (partially printed in 1903 in Charles Hughes's Shakespeare's Europe). Another part of the Itinerary was republished in 1735 with the title History of Ireland 1599-1603, with a short Narrative of the State of the Kingdon from 1599; and in 1800 Henry Morley included in the "Carisbrooke Library" a volume, Ireland under Elizabeth and James I., described by Spencer, Sir John Davies and Fynes Moryson. The Itinerary was a work of great value to the historian as a truthful picture of the social conditions prevailing in Europe at the beginning of the 17th century.

Mosaics (corresponding to Lat. opus musicum, from Gr. μοιρησμος, an artificial grotto often decorated with mosaics; the word is only found in the sense of mosaic in late Greek, which generally uses φυλλοδεματος), the fitting together of many, generally small, pieces of marble, opaque glass, coloured clays, or other substances, as so as to form a pattern.

Ancient Mosaic.—The earliest existing specimens of mosaic belong to one of the less important branches of the art—namely, the ornamentation on a small scale of jewellery, ivory thrones, and other furniture, or more rarely of some elaborate architectural ornament. Most of this sort of mosaic resembles in execution what are called cloisonné enamels. In the Louvre and in the British Museum are preserved some very beautiful ivory carvings in low relief, some from Nineveh and others from Egypt, in which figures of deities, ornaments formed of the lotus and papyrus plants and royal cartouches are enriched by small pieces of glass, or lapis-lazuli and other gem-like stones, which are let into holes made in the ivory. Each minute piece is separated from the next by a thin wall of cloison of ivory, about as thick as cardboard, which thus forms a white outline and sets off the brilliance of the coloured stones.

Excavations at Tel-el-Yehudia in Lower Egypt have brought to light some mosaics on a larger scale, but treated in the same way. These are caps of columns, wall tiles, and other objects, either of white limestone or earthenware, in which designs, chiefly some forms of the papyrus, are formed by bits of glass or enamelled earthenware, let into a sinking in the tile or column. This form of mosaic was employed by the Greeks: the Erechtheum at Athens, built in the middle of the 5th century B.C., had the bases of some of its white marble columns ornamented with a plait-like design, in which pieces of coloured glass were inserted to emphasize the main lines of the pattern.

Another, quite different, sort of mosaic was known to the Egyptians of the Ptolemaic and Roman periods. This is made entirely of glass and is extremely minute. The finest known specimen is in the British Museum: it is a small table about ¼ in. square, apparently the bezel of a ring, on which is represented the sacred hawk—every feather on the bird's wings being produced with a great number of colours and tints, each quite distinct, and so minute that a strong magnifying glass is required to distinguish its details.

The way in which this mosaic was produced is extremely ingenious. Numbers of long sticks of various-coloured glass were arranged in such a way that their ends produced the figure of the hawk; other sticks of blue glass were placed all round so as to form the ground. The whole bundle of sticks of glass when looked at endwise now presented the figure of the hawk with a blue background, immensely larger than it afterwards became. The bundle was then heated till the sticks melted together, and the whole thick rod, softened by fire, was drawn out to a greatly diminished thickness. A slice of the rod was then cut off and its faces polished—the design, much reduced in size, of course being equally visible at both sides of the slice; and thus the microscopic minuteness of the mosaic was produced with astonishing delicacy and refinement; many slices, each showing the same mosaic, could be cut from the same rod.

The most important was the use of mosaic on a large scale, either for pavements or for walls and vaulted ceilings. We are told by Pliney (II. N. xxxvi. 184) that the practice of decorating pavements "after the fashion of painting" was due to the Greeks, and there is no reason to doubt the truth of this statement, although no mosaic pavement discovered in Greece can be dated with certainty to a period preceding the Roman occupation. This is true even of the pavement in the temple of Zeus at Olympia (fig. 1; Olympia, Baudenmöller, vol. ii. pl. cv.).
MOSAIC

The simplest classification of mosaics is that of Gauckler (Daremberg and Saglio, Dictionnaire des antiquités, s.v. "Musium Opus"), who distinguishes the following:

a. Opus tessellatum, consisting of cubes of marble or stone, regularly disposed in simple patterns. This was largely used for pavements, especially in Roman times.

b. Opus vermiculatum, consisting of cubes (not always regularly shaped) generally of coloured marble or more precious materials, when these were obtainable, disposed so as to obtain a pictorial effect. The art of mosaic is mainly concerned with this branch of work.

c. Opus musivum, properly applied to the mosaic decoration of walls and vaulted ceilings (camiere), in which cubes of glass or enamel were used. The glass was rendered opaque by the addition of oxide of tin, and coloured with other metallic oxides; when melted it was cast into flat slabs, generally about \( \frac{1}{2} \) in. thick, and then broken into small cubes.

d. Opus sectile, a species of marquetry in marble or other coloured materials used to produce pictures and patterns. Under the later empire a particular variety of this, called opus alexandrinum, mainly composed of porphyry, red and green, was much in use.

Judging from the description given by Vitruvius (vii, 1), and an examination of numerous specimens of Roman tessellated mosaics, the process of manufacture was the following. The earth was first carefully rammed down to a firm and even surface; on this was laid a thick bed of stones, dry rubbish, and lime, called "rudus," from 6 to 9 in. deep, and above this another layer, 4 to 6 in. thick, called "nucleus," of one part of lime to three of pounded brick, mixed with water; on this, while still soft, the pattern could be sketched out with a wooden or metal point, and the tesserae or small bits of marble stuck into it, with their smoothest side uppermost. Lime, pounded white marble, and water were then mixed to the consistency of cream, forming a very hard-setting cement, called marmoratum. This cement, while fluid, was poured over the marble surface, and well brushed into all the interstices between the tesserae. When the concrete and cement were both set, the surface of the pavement was rubbed down and polished.

The usual Roman pavement was made of pieces of marble, averaging from half a quarter of an inch square, but rather irregular in shape. A few other, but quite exceptional, kinds of mosaic pavements have been found, such as that at the Isola Farnese, 9 m. from Rome, made of tile-like slabs of green glass, and a fine "sectile" pavement on the Palatine Hill, made of various-shaped pieces of glass, in black, white, and deep yellow. In some cases—e.g. in the "House of the Faun" at Pompeii—glass tesserae in small quantities have been mixed with the marble ones, for the sake of greater brilliance of colour.

Few countries are richer than England in remains of Roman mosaics; the great pavements at York, Woodchester, Cirencester, and many other places are as elaborate in design and as skilfully executed as any that now exist even in Rome itself. In whatever country these mosaics are found, their style and method of treatment are always much the same; the materials only of which the tesserae are made vary according to the stone or marble supplied by each country. In England, for instance, limestone or chalk often takes the place of the white marble so common in Italian and North African mosaics; while, instead of red marble, a fine sort of burnt clay or red sandstone is generally used; other makeshifs had to be resorted to, and many of the Romano-British mosaics are made entirely without marble. It is perhaps partly owing to the great wealth of Northern Africa in marbles of many colours and of varying shades that the finest of all Roman mosaics have been found in Algeria and Tunis, especially those from Carthage, some of which have been brought to the British Museum. See Archaeologia, xxxviii. 202.

The range of colour in the marble tesserae is very great, and is made use of with wonderful taste and skill: there are three or four different shades of red, and an equal number of yellows and greens, the last colour in all its tints being almost peculiar to this part of Africa, and one of the most pleasant and harmonious in almost any combination. Deep black, browns and bluish-greys are also abundant. The mosaics from Carthage are no less excellent in design than in the richness and beauty of their materials. Large spaces are filled by grand sweeping curves of acanthus and other leaves, drawn with wonderful boldness and freedom of hand, and varied with great wealth of invention. Without the use of very small tesserae, much richness of effect is given by gradations of tints, suggesting light and
shade, without a painful attempt to represent actual relief. The colours of the marbles used here and elsewhere by the Romans are so quiet and harmonious that it would be almost impossible to produce with them a harsh or glaring design, and when used with the skill and strong artistic feeling of the mosaic workers at Carthage the result is a real masterpiece of decorative design.

The finest of the later examples in Rome is that which decorates the mausoleum of the Emperors Hadrian and Sabina, at Tivoli. This very interesting mosaic might from its style and materials have been executed in the 1st century, and is equal in beauty to any work of the kind in Italy. It shows no trace whatever of the Byzantine influence which, in the next century, introduced into Italy a novel style of mosaic, in materials of the most glittering splendour. Survivals of this classical style of mosaic are found in North Africa and the Near East; as at Kabr-Hiram, near Tyre. Ravenna discovered among the ruins of a small three-apsed Christian church of the 5th century A.D. a fine mosaic pavement, covering the nave and aisles, thoroughly classical in style. A very similar mosaic, of about the same date, was discovered at Nebi Yünas, near Sidon.

**Medieval Mosaics** — These may be divided into four principal classes: (1) those used to decorate walls and vaults, made of glass cubes; (2) those for pavements, made of marbles, partly in large shaped pieces, and partly in small tesserae; (3) glass in small pieces, either rectangular or triangular, used to enrich marble pulpits, columns, and other architectural features; (4) wood mosaics.

1. In the Byzantine period the glass cube mosaic was exclusively employed in mural decoration. At first natural colouring was used, and backgrounds, if not in local colour, were generally blue; but the use of gold, both for backgrounds and for the high lights on drapery, &c., gradually prevailed. Owing to the intense conservatism of Byzantine art, no regular stages of progression can be traced in this class of mosaic. Some of the 5th-century mosaics at Ravenna are, in every way, as fine as those of the 12th, and it was not till the end of the 13th century that any important change in style took place. The mosaics of the 9th century are inferior in drawing and general treatment to those both of the earlier and later time, while in Italy at least this art was almost entirely extinct during the 10th and 11th centuries. Extreme splendour of colour and jewel-like brilliance combined with the most stately grandeur of form are the main characteristics of this sort of decoration.

A "majesty," or colossal central figure of Christ with saints standing on each side, is the most frequent motive. In many cases, especially in the 5th and 6th centuries, Christ was represented as a lamb, to whom the twelve apostles, in the form of sheep, are paying adoration. Christ, the Good Shepherd, is sometimes depicted as a beardless youth, seated among a circle of sheep—the treatment of the motive being obviously taken from pagan representations of Orpheus playing to the beasts. The tomb of Galla Placidia has a good example of this subject, with much of the old Roman grace in the drawing and composition. Frequently the Virgin Mary, or the patron saint of the church, occupies the central space in the apse, with ranges of other saints on each side.

The "Doom," or Last Judgment, is a favourite subject for domes and sacristy arches; the Florence baptistery has one of the greatest mosaic pictures of this subject, executed in the 13th century. The earlier baptistaries usually have the scene of Christ's baptism—the river Jordan being sometimes personified in a very classical manner, as an old man with flowing beard, holding an urn from which a stream pours forth. S. Vitale at Ravenna has in the sanctuary a very interesting representation of Justinian and his empress Theodora (see fig. 3), attended by a numerous suite of courtiers and ladies; these were painted about the middle of the 6th century, and may be contemporaneous with Justinian, though the fact that he and Theodora are each represented with a circular nimbus appears to indicate that they were not then alive.

In mosaics of the best periods the treatment of the forms and draperies is broad and simple, a just amount of relief being expressed by different gradations of tints. In mosaics of the 9th century the drawing is very awkward, and the folds of the robes are rudely expressed in outline, with no suggestion of light and shade.

A further application of this work was the decoration of broad bands over the columns of the nave, as at S. Maria Maggiore in Rome, 4th century, and in the two churches of S. Apollinare at Ravenna, 6th century. In some cases almost the whole interior of the church was encrusted in this magnificent way; as at Monreale Cathedral, the Capella Palatina of Palermo, and S. Mark's at Venice.

In these churches the mosaics cover soffits and angles entirely, and give effect of a mass of solid gold and colour producing the utmost conceivable splendour of decoration. In many cases vaulted ceilings were covered with these mosaics, as the tomb of Galla Placidia, A.D. 450, and the two baptistaries at Ravenna, 5th and 6th centuries. For exteriors, the large use of mosaic was usually confined to the west façade, as at S. Miniato, Florence; S. Maria Maggiore, Rome; and S. Mark's, Venice. In almost all cases the figures are represented on a gold ground, and gold is freely used in the dresses and ornaments—rich jewelled and embroidery being represented in gold, silver, sparkling reds, blues and other colours, so as to give the utmost splendour of effect to the figures and their drapery.

The revival of the art of painting in Italy and the introduction of fresco work in the 14th century gave the deathblow to the...
true art of wall-mosaics. Though at first the simple and archaic style of Cimabue and his pupils Jacopo da Turrata, Giotto, and Taddeo Gaddi was equally applicable to painting or mosaic, yet soon the development of art into greater realism and complexity required a method of expression unfettered by the necessities and canons of mosaic work. Pietro Cavallini, a Roman artist, was one of the last who worked according to the old traditions. His mosaic of the birth of the Virgin in S. Maria in Cosmedin, Rome, executed about the middle of the 14th century, is not without merit, though his superior knowledge of form has only caused his composition to be somewhat feeble and insipid compared with the works of the earlier artists. Even in the 14th century a few good mosaics were produced at Venice and elsewhere. The mosaics from Titian's pictures on the west end of S. Mark's at Venice, Raphael's in the Chigi Chapel in S. Maria del Popolo, and many large pictures in S. Peter's in Rome are the most striking examples of these.

The following list, in chronological order, comprises a selection from among the most important glass mosaics during the period when mosaic-working was a real art.\(^1\)

\(^1\) It must be remembered that the earlier mosaics have in most cases suffered much from restoration.

The first and second mosque mosaics, though of great beauty, are of less artistic importance. This so-called *opus alexandrinum* is very common throughout Italy and in the East, and came to greatest perfection in the 14th century. It is made partly of small marble tesserae forming the main lines of the pattern, and partly of large pieces used as a ground or matrix. It is generally designed in large flowing bands which interlace and enclose circles, often of one stone sliced from a column. The finest example is that at S. Mark's, Venice, of the 12th century. The materials are mainly white marble, with green and red porphyry, and sometimes glass.
Besides the countless churches in Italy possessing these beautiful pavements, such as S. Lorenzo, S. Marco, S. Maria Maggiore, and S. Maria in Trastevere, in Rome, there are in England, in the Chapel of the Confessor, and in front of the high altar at Westminster, very fine specimens of this work, executed about 1268 by a Roman artist called Odericus, who was brought to England by Abbot Ware, on the occasion of a visit made by the latter to Rome. Another English example is the mosaic pavement in front of the shrine of Becket at Canterbury; this is probably the work of an Englishman, though the materials are foreign, as it is partly inlaid with bronze, a peculiarity never found in Italy. Palermo and Monreale are especially rich in examples of seccile mosaic, used both for pavements and walls—in the latter case generally for the lower part of the walls the upper part being covered with the glass mosaics. Fig. 4 gives a specimen of this mosaic from Monreale cathedral. Its chief characteristic is the absence of curved lines, so largely used in the splendid opus Alexandrinum of Italy, arising from the fact that this class of Oriental design was mainly used for the delicate panelling in wood on their pulpits, doors, &c.—wood being a material quite unsuited for the production of large curves.

3. Glass mosaic, used to ornament ambones, pulpits, tombs, bishops’ thrones, baldacchini columns, architraves, and other marble objects, is chiefly Italian. The designs, when it is used to enrich flat surfaces, such as panels or architraves, are very similar to those of the pavements last described. The white marble is used as a matrix, in which sinkings are made to hold the glass tesserae; twisted columns are frequently ornamented with a spiral band of this glass mosaic, or filstings are suggested by parallel bands on straight columns. The cloisters of S. Giovanni in Laterano and S. Paolo fuori le mura have splendid examples of these enriched shafts and architraves. This style of work was largely employed from the 6th to the 14th centuries. One family in Italy, the Cosmati, during the whole of the 13th century, was especially skilled in this craft. The pulpit in S. Maria in Ara Coeli, Rome, is one of the finest specimens (see fig. 3), as are also the ambones in S. Clemente and S. Lorenzo, and that in Salerno cathedral. The tomb of Henry III. (1216), and the shrine of the Confessor (1296) at Westminster are the only examples of this work in England. They were executed by “Petrus civis Romanus,” probably a pupil of the Cosmati.

In India, especially during the 17th century, many Mahomedan buildings were decorated with fine marble inlay of the class now called Flosintes. This is seccile mosaic, formed by shaped pieces of various coloured marbles let into a marble matrix. A great deal of the Indian mosaic of this sort was executed by Italian workmen; the finest examples are at Agra, such as the Taj Mahal.

4. Mosaics in wood are largely used in Mahomedan buildings, especially from the 14th to the 17th centuries. The finest}

specimens of this work are at Cairo and Damascus, and are used chiefly to decorate the magnificent pulpits and other woodwork of the mosques. The patterns are very delicate and complicated, worked in inlay of the pieces of various coloured woods, often further enriched by bits of mother-of-pearl and minutely carved ivory. This art was also practised largely by the Copts of Egypt, and much used by them to ornament the magnificent iconostases and other screens in their churches.

Another application of wood to mosaic work, called “intarsia,” was very common in Italy, especially in Tuscany and Lombardy, during the 15th and early 16th centuries. Its chief use was for the decoration of the stalls and lecterns in the church choirs. Very small bits of various coloured woods were used to produce geometrical patterns, while figure subjects, views of buildings with strong perspective effects, and even landscapes, were very skilfully produced by an inlay of larger pieces. Ambrogio Borgognone, Raphael, and other great painters, often drew the designs for this sort of work. The mosaic figures in the panels of the stalls at the Certosa near Pavia were by Borgognone, and are extremely beautiful. The stalls in Siena cathedral and in S. Pietro de’ Casinensi at Perugia, the latter from Raphael’s designs, are among the finest works of this sort, which are very numerous in Italy. It has also been used on a smaller scale to ornament furniture, and especially the “Cassoni,” or large trousseau coffers, on which the most costly and elaborate decorations were often lavished.

AUTHORITIES.—Classical. An excellent account of the subject, with full references, is given by Gauckler in Darmenberg and Saglio, Dictionnaire des antiquités, s.v. “Musivum opus”; the translations there given of the loci classici of Pliny are, however, inaccurate. Among the earlier works the following are important: G. Ciampi, Sagra monastica, vetera monasteria (1752); S. Lysons, Roman Antiquities of Woodchester (1797) and Reliquiae Britannicae (1839); F. Mazois, Ruines de Pompeï (1812–1815); E. P. Artaud, Histoire de la peinture en mosaïque (1835); Monuments archéologiques de l’España (1859–1883); Wilmsowsky, Römische Mosaike aus Trier und dessen Umgebung (1883).

fig. 5.—Part of Marble Pulpit with glass mosaic, church of Ara Coeli, Rome.
Modern Mosaic.—The art of mosaic for mural decoration has never been deeply implanted in the artistic sensibilities of the north of Europe, nor has it been employed much either in France, or Germany, or England. It ceased to be generally adhered to in Italy when fresco, oil and tempera painting came into vogue. Gothic architecture is ill-suited to its robust claims as a decorative art; and the incoming fashion for the latest and least interesting development of classical architecture, “Palladian,” divorced not only it, but mural painting also, from all architectural schemes. To be properly consequent and effective, buildings, ecclesiastical or public, should be constructed with the intention of being covered almost entirely by mosaics, which demand rich environment, marble or other colour; mosaic is essentially a colour medium. It is therefore scarcely surprising that when mural decoration became pre-eminently pictorial, and gestures and expression grew complicated, elaborate, and naturalistic, an art limited in its powers of presenting such manifestation of realistic design was relegated into the limbo of obscurity.

There are no instances of the use of mosaic in England after the Roman occupation. The Normans, who derived it from the Greeks and Saracens, and adopted it in Sicily, did not import it either to Rome, France or England. Although English churches, and French also, were highly decorated with polychromy from early times up to the 16th century, there is no evidence of mosaic ever having been used. The revival of a school of mosaicists in Rome during the 17th century, employed in the decoration of St Peter’s, and here and there sparsely engaged in other churches, led to the idea which Wren would have carried into effect, namely, making use of mosaic for the cathedral of St Paul’s in London; but his scheme, if it was ever really entertained, was not carried out, as we all know; and the art, which might have become the fashion in England, remained an exotic. Even late in the years of the 19th century mosaic decoration was regarded by classical purists as a barbarous art, and the glorious decorations in that material to be seen in Sicily, Italy, Greece, Asia Minor and Russia were disregarded as works of high art. They were in many cases cut out to provide room for extravagant and vulgar designs in fresco or tempera, unmeaning, undecorative, and wholly abominable as decoration. Those Roman mosaics over the altars in St Peter’s, being copies of celebrated oil paintings, while they cannot be denied excellence as such and marvellous dexterity, reveal the worst possible taste, for they attempt to represent adequately, in cubes, touches of the brush which were spontaneous, fluid, thick and thin, and as sensitive and spontaneous as the finger pressure on the violin string, so accurate that the least deviation from absolute position produces discord.

The restrictions on mosaic are many, and some are obvious. In the first place, mosaic is not suited for a small scale of design. It is true that in the Opera del Duomo in Florence there is a miniature mosaic (executed in the 12th century) of extraordinary beauty, which must have taken a lifetime to execute; but still this remains a curiosity, a bit of craftsmanship rather than a great work of art. There is also a copy of Mr Holman Hunt’s “Finding the Saviour in the Temple,” executed for Clifton College by assistants in Messrs Powell’s establishment in Whitefriars, London; it is admirably done, no doubt, but it is a way behind the original, which is a design wholly ill adapted to mosaic. There are several other instances, notably one by Mr H. Holiday of “The Last Supper,” where mosaic has been employed to translate a beautiful design which would have been more satisfactorily executed either in oil or water colours. The primal and most obvious limitation is in matters of detail—detail as regards a multiplicity of forms, many gradations either of colour or tone and naturalistic accidents. In this respect good mosaic is like good baso relievo; it is accomplished by firmly pronounced outlines, unconfused masses, large planes unbroken up by small adjuncts, and generalized and conventionalized forms and simple colour. So all small curves, as well as small tints, should be eliminated, because it is not in the nature of the material to do them justice. One can scarcely conceive a choice less happy for mosaic than the centre group taken out of the upper portion of the Disputa fresco in the Vatican by Raphael, yet this florid piece of work, so facile in creation, was chosen to be executed on the eastern wall of the morning chapel in St Paul’s.

It is useless to illustrate the many similar mistakes that have been made. They were made in some of the earlier work in the choir of St Paul’s. The best example of mosaic on a small scale is in Ravenna, the tomb of Galla Placidia; the best upon a large scale is the great Christ at the east end of the cathedral at Monreale. These two works absolutely justify the means to the end. Interesting are the designs made by Sir Edward Burne-Jones for the mosaics for the American church in Rome, but the execution and colour are alike monotonous. The cathedral of Chester contains a series of mosaic pictures designed by Mr Clayton. The Guards’ chapel in St James’s is adorned likewise by the same artist, under the direction of the late Sir Arthur Blomfield. In the chapel for the school at Giggleswick are mosaics designed by T. G. Jackson, R.A., admirably and broadly treated in true mosaic character; these were executed in situ, and therefore freed from all the restrictions of paper, cloth or any aid, except that of the artist’s own imagination, and the creation of a perfect work of art, upon paper, a way from their environment and by a foreign firm. Those mosaic pictures which are placed in niches in the great gallery of South Kensington Museum are failures of mosaic, though the designs in many instances are fine, notably those by Lord Leighton and Val Prinsep; but their execution is uninteresting, because the cubes are laid so flatly and so evenly that they suggest an oil picture applied upon a flat ground.

Messrs Powell have been employed on several occasions to decorate churches with mosaic. This firm has adopted the old style, and rejected the new one initiated by Dr Salvati of Venice. If we observe the surface of a fine Greek mosaic, such as that of Andrea Tafi in the Baptistery of Florence, or the few remains of unrestored mosaic in St Mark’s, Venice, or indeed other works scattered over Italy, we shall see that it is rough, not smooth; that the cubes are irregular in shape; that there is always a space of the ground colour left, red or white, and visible between each cube. In modern mosaic, with rare exceptions, restoration or other, the cubes have been jammed up closely together, and the surface is as smooth as a piece of paper; thereby it is engendered a mechanical and uninteresting surface, over which light plays with monotonity, and hence that brilliant and scintillating effect so essentially the character of true mosaic is absent. This defect—and it is a grave one—is evident in the works in mosaic more or less recently set up in Paris, notably in the apse of the Pantheon, the east end of the Madeleine, and the vaulting of the great staircase of the Louvre. Those in the apse are finely designed, but scarcely look like mosaic, those in the Madeleine still less so, and the last not at all.

The artist who designs for this material must set aside all the principles he has learned to estimate in paint, either of oil or tempera. As an instance of a painter, pre-eminently delicate in his colour and tone, failing as a mosaic designer we may quote Cimabue, whose beautiful designs in the cathedral at Pisa would have been far more effective had the artist painted them upon the wall with the medium in the requirements of which he was so great a master. The same criticism may apply to the mosaics executed in recent years set up on the west front of Santa Maria del Fiore in Florence. The very first principles which go to make a fine picture are just those which should be avoided in mosaic—elaborate modelling, delicate transitions of light and shade and picturesque effects of dark and light, materialistic resemblance indeed. The designer for mosaic should ever bear in mind his material, and in his designs for it he should accentuate those characteristics which belong essentially and specifically to mosaic and to no other technique. If he is a painter, he must forget his lessons in that art and take up with new ones—those which teach broad masses of colour obtained in lines. He will find that effects gained by a technique employed in oil colour look bald and ridiculous when translated into mosaic. Watercolour and pastel are by far the best media for cartoons to be copied in mosaic. We do not know how these were executed
in ancient days; probably the design was drawn on the wall, and there were no cartoons. The master not only invented, but he was the master-workman also, and that is how it should be. The probability is that the custom of drawing the design upon the wall practised by the early frescanti was the survival of a method adopted by the mosaicists, just as their method repeated that of Roman and Greek wall-painters. Of course this direct method leads to a large style, a style harmonizing with environment, scale, &c.; the tendency is to draw large in a large building, to draw small in a small one. Anyhow, this is quite certain, that all the fine Byzantine and 17th century mosaics, as well as wall paintings, were executed in situ and not away, as was the usual custom in England and elsewhere until recently.

The mosaicist has to make use of some of his reflections upon the mosaicist's art in the following notes. The mosaicist should not separate the artistic from the technical details of his craft. He must not study only the decorative effect, form, colour and spacing of his design, but the surface to be covered as well as the materials with which he builds.

Surface.—Good brick-work, the mortar joints slightly cut back, affords the best foundation for mosaic. The hollow and sharp-edged joints provide a key for the cement into which the cubes will fit, and the result is a very strong bond, a notable additional event if the cement is not welded to the wall by being well pressed into the joints. If the mosaic is to be applied on stone, the stone must be notched and well roughened to provide support. Whether the cement be laid on stone or masonry, or be joined upon the wet wall to prevent suction, because if too much suction takes place the powder only of the cement will remain and the cubes will drop out.

Concrete suitable for mosaic is oxide of lime which contains intensity, which can be applied in layers, which sets slowly, and which is not liable to change colour after long exposure. These conditions are best met by an oil cement. One consisting of equal weights of white oxide of zinc and carbonate of lime, mixed with double boiled oil and containing small proportions of wax, gold oxide and slaked lime gives good results. This cement can either be white or red, white where greyness of tone is desirable, red where a richer effect is required. It is generally mixed either with a small proportion of oxide of iron or oxide of manganese, which prevents the whiteness of the joints from rendering adjacent tints grey from a distance.

Atmospheric Corrosion.—As the atmosphere of modern towns is more corrosive than that of medieval Venice or medieval Rome, it is important that, in choosing the cement and the materials to be imbedded in it, the mosaicist should be certain that they are impervious to atmospheric impurities.

Glass.—Mother of pearl, and other substances have been, and are still, occasionally used, the predominant material in ancient as well as modern mosaics is glass. When prepared with due regard to the continuing proportions of its ingredients, glass is impervious to the attack of organic or inorganic agents. It is indestructible. It can be made to assume almost every shade and tint of colour (see Glass). There are many kinds of glass, but for mosaic work either a potash-leaf or a soda-lime glass is usually employed. Two kinds of these glasses can be rendered suitable by mixing with the ingredients either oxide of tin or a mixture of felspar and fluor spar. Glass rendered opaque by the admixture of felspar and fluor spar has a bright, vitreous, easily cleaned surface, and readily develops brilliant colours.

Production of Colours.—Colours are obtained by mixing and melting with the ingredients of the opaque glass small proportions of certain metallic oxides. Oxide of chalk gives a purple blue; oxide of copper green; oxide of copper green; oxide of copper mixed with oxide of iron and a strong reducing agent gives a red; oxide of chromium a green; oxide of nickel with a little of uranium a yellow; and oxide of manganese a violet—or a black if a larger quantity of oxide is used.

Manufacture of Glass Slabs.—The mixtures, in a state of powder, are subjected to crucibles standing round the grate of a furnace, and when fusion is complete the viscous glass can be collected up from the heated end of an iron rod and removed for use, very much in the way that thick treacle may be coiled round the bowl of a spoon. A mass of the collected glass can be allowed to fall upon a flat iron table, and is pressed into a slab about 6 in. square and 

\[ \frac{1}{4} \text{ in. thick.} \]

The slabs are removed to an oven, where they are allowed to cool slowly, and when cool are removed and broken by a sharp blow with a hammer, until a small square slab is obtained. The fractured edge of the tesserae is used for the surface of the mosaic.

Gold and Silver Slabs.—The tesserae containing gold or silver leaf are as impervious to surface corrosions from the effects of atmosphere as the solid colours. The process of manufacturing a gold or silver slab for mosaic work is to spread the metallic leaf on a very thin tray of transparent glass, about 5 in. in diameter, and after it has been heated to press upon the surface of the leaf a mass of molten glass, so as to create cohesion between the molten glass and the glass tray through the pores of the metallic leaf. The slabs thus formed contain gold, silver or platinum leaf hermetically imprisoned between layers of glass. The slabs are cut up into tesserae or cubes by means of a diamond or glass-cutter's wheel.

Only one surface can be used for mosaic work.

Drawing directly on the Wall. Curved Surfaces.—If the mosaicist desires to draw his cartoon directly upon the wall, a necessary procedure where curved surfaces are presented, he goes to work in the following manner. He causes a model to be made to scale of a dome, semi-dome or spandrel and upon it he draws his design with a brush in strong red pigment, having previously warmed up the whole model to a red heat. This done, he causes the dome, semi-dome or spandrel to be covered with a sheet of black brown paper. This being attached to the wall with white lead sufficiently to give temporary adhesion, the brown paper is squared up to the scale of the small sketch; each square being relatively numbered. The master then sets his pupils to work to draw mechanically and copy accurately from the small design on to the full-sized dome, semi-dome or spandrel. This done, the master follows on, correcting with charcoal or brush until the whole design is developed in strong outline. Having made a slightly coloured sketch, the master with the aid of his pupils proceeds to mix all the tints in water-colour, adding
delle pesce or fish glue, and a little honey to prevent cracking. He then applies every tint separately, keeping each distinct, and above all mind that the local colours of all half-tints are different from the colour of all shadows. This done, he dips his brush in black and draws all the outlines, the thickness of which depends upon the distance which will intervene between his work and the spectator; in order that the black may not appear cold from a distance, he will add to one side of the line, a red line, thicker or thinner than the black, according to the effect he wishes to produce. It is sometimes effective to add upon the other side of the black line a green line, so that the purple effect of the black and red shall be modified.

Colour.—We now come to the great question of colour and how to obtain it simply, and so that from a distance a blunted and woolly effect is not obtained. There should be a marked and sharp definition between all tints; they should not be fused; they should look sharply defined, as the shadow upon a chessboard, and appear crude and brutal. The work which looks least refined near at hand looks more finished at a distance. Red and blue lines alternately laid, either more red or more blue as the purple is intended to tend towards red or blue, make the best purple. Green is best made with yellow and blue lines, the masses being separated by red lines, and the shadows of green should be red or blue; if red, they should be outlined with blue; if blue, with red. Red should be treated flatly, shaded with a deeper red, which should be of a warmer tone than the lights. Blue should be shaded with blue or red; and it is well to mix green tesserae with the blue in the lights, and again green tesserae with either red or blue shades to modify crudity. Pure white should be very sparingly used; it expands upon grey, and gives a dirty effect. The best white is that which is of the tone of Naples yellow. Whenever it is necessary to use pure white, either a yellow or pink line should be set on one side of it. It is impossible to keep the flesh too simple. The local colour, i.e. a red orange, is the staple colour. Features should be drawn
in strong red or burnt sienna, or a rich brown. The outlines of limbs or the contours of faces should be made first with a green line, a little darker than the local tints, then a red line darker still, then a black or brown line. White draperies are capable of being treated with endless variety. Their shades may be green, red, blue, grey or yellow. If the white drapery is to take a neutral tone when seen from a distance, all these tints should be employed, because when mixed those positive colours appear neutral when seen from afar.

Gold drapery has a fine effect. Bright gold expands to four times the width of the line, so that the lines of gold should be thin. It may be that the gold drapery is to appear greenish; when that is desirable the folds should be drawn in green outlined with red. All deep shades should be treated with red and hot browns. As gold expands so considerably, a larger interval should be left between the tesserae than between any other colour, even white. Each tessera should have a thin space of the ground colour round it. The tesserae should never be jammed: it is that which causes so many modern mosaics to look like oil-cloth or chromo-lithographs.

The Finished Cartoon.—The finished cartoon, having been coloured in lines, should look exactly like the finished mosaic as regards effect; and the master, in making his cartoon, should always bear in mind that he is designing for mosaic, and not making a finished picture. The cartoon, when complete, is taken off the wall and cut up in pieces. Each piece is then carefully traced. The space upon the wall corresponding to each section is then covered with cement, but only upon that portion of the space which can be worked in mosaic in a day. The mosaic worker then applies the portion of the tracing upon the wet cement, and with a sharp point he pricks through the paper upon the lines thereon drawn; on removing the tracing he will find indents within the surface of the cement, which give him his cue to all the forms. Setting up the coloured design by his side, he takes the tesserae, which exactly correspond in colour and tone to those on the drawing, and begins his work, commencing from the outline and working towards the centre, the lightest portion being left to the last. Here comes in the real test whether the craftsman is capable of or the reverse. This is soon judged by the master, who will put the work in and out until he is satisfied with the result. Unless the master has himself gone through the drudgery of laying the cubes he can be no teacher. He must be a craftsman as well as a designer, and must know by experience and practice in a very difficult craft what the material can do with ease and what it is not called upon to do by reason of its inherent limitations. If he has not so trained himself he is certain to pictorialize what he should conventionalize; and, moreover, he will set technical difficulties in the way which are impossible to overcome. He must aim at the greatest simplicity without dullness, at producing the greatest effect by the simplest means, and to do that he must know his material or fail. (W. B. R.)

MOSBY—JOHN SINGLETON.—American soldier, was born in Edgemont, Powhatan county, Virginia, on the 6th of December 1833. He graduated at the university of Virginia in 1852, was admitted to the bar in 1855, and practised law in Bristol, Washington county, Virginia, until the beginning of the Civil War, when he joined the cause of the South. He enlisted as a private in the Washington Mounted Rifles, which became a part of General J. E. B. Stuart's 1st Virginia Cavalry, and of which he was adjutant for a time. In June 1862, after having gone over the ground alone on scouting duty, he accompanied Stuart in his ride round McClellan's entire army. Early in 1863 he secured Stuart's permission to undertake a quasi-independent command. In Fairfax county and then in Fauquier and Loudoun counties (known as Mosby's Confederacy), within the Federal lines, he raised, mounted, armed and equipped a force of irregulars. On the night of the 8th of March 1863, with about 20 men, he penetrated the Federal lines at Fairfax Court-House and took 33 prisoners, including Brigadier-General Edwin H. Stoughton, commanding the 2nd Vermont brigade; and he became famous for other such exploits. In the North

he was regarded as a guerrilla who disregarded the rules of war, and in the autumn of 1864, Sheridan, acting under orders from Grant, shot and hanged seven of Mosby's men without trial; in November Mosby retaliated by hanging seven of Custer's cavalrymen. Eventually, on the 21st of April 1865, twelve days after the surrender of General Lee, he disbanded his men and surrendered; and through the influence of General Grant, who later became his personal friend, he was paroled. He returned to his legal practice, joined the Republican party, canvassed Virginia in 1872 for General Grant, in 1878–1885 was United States consul at Hong-Kong, and after practising law in San Francisco, was assistant attorney in the Federal Department of Justice from 1904 to 1910. He wrote Mosby's Reminiscences and Stuart's Cavalry Campaigns (Boston, 1887), and—a defence of Stuart and of Lee—Stuart's Cavalry in the Gettysburg Campaign (New York, 1908).

See J. Marshall Crawford, Mosby and his Men (New York, 1867); A Memoir of War Reminiscences by the Surgeon Gen'l. Mosby's Command (Richmond, Virginia, 1890); James J. Williamson, Mosby's Rangers (New York, 1909); John W. Munson, Reminiscences of a Mosby Guerilla (New York, 1906); John H. Alexander, Mosby's Men (New York, 1907); Mosle Life with Mosby (New York, 1867), by John Scott, who drafted the Partisan Ranger law, under which Mosby's command operated.

MOSCHELES, IGNAZ (1794-1870), Bohemian pianist, was born at Prague on the 30th of May 1794, and studied music at the Conservatorium under the direction of Dionys Weber. At the age of fourteen he made his first appearance before the public in a pianoconcerto of his own composition with marked success. In 1814 he prepared, with Beethoven's consent, the pianoconerto arrangement of Fidelio, afterwards published by Messe Artaria. In the following year he published his celebrated Variationen über den Alexandermarsch, a concert piece of great difficulty, which he played with so great effect that he was at once recognized as the most brilliant performer of the day. He then started on a tour, during the course of which he visited most of the great capitals of Europe, making his first appearance in London in 1829, and there securing the friendship of Muzio Clementi and John Cramer. For a concert given by the latter he wrote his famous Hommage à Händel, a duet for two pianofortes, which afterwards became a lasting favourite with the public. During a visit to Berlin in 1824 he first became acquainted with Mendelssohn, then a boy of fifteen; and a friendship sprung up between them which was severed only by Mendelssohn's early death (see Briefe von Mendelssohn-Bartholdy an Ignaz und Charlotte Moscheles, 1888). In 1826 Moscheles married Charlotte Embden at Hamburg, and settled permanently in London. He was undoubtedly for some considerable time the greatest executant of his age; but, using his brilliant touch as a means and not as an end, he consistently devoted himself to the further development of the true classical school, interpreting the works of the great masters with conscientious fidelity, and in his extempore performances, which were of quite exceptional excellence, exhibiting a fertility of invention and a broad and buoyant cast of mind. In 1857 Moscheles conducted Beethoven's Ninth Symphony at the Philharmonic Society's concerts with extraordinary success, and by his skilful use of the bitten contributed to the prosperity of this association. During the course of his long residence in London he laboured incessantly in the cause of art, until the year 1846, when, at Mendelssohn's earnest solicitation, he removed to Leipzig to carry on a similar work at the Conservatorium, then recently founded. In this new sphere he worked with unabated zeal for many years, dying on the 10th of March 1870. Moscheles' numbered works extend to 142, apart from minor pieces; his most important compositions are his Pianoconcertos, Sonatas and Studies (Studes, op. 70; and Characteristische Studien, op. 95; Hommage à Händel; and his three Allegri da bravura). See The Life of Moscheles (1873), a translation by A. D. Coleridge of Mme Moscheles' Aus Moscheles Leben (1872).

MOSCHEROSCH, JOHANN MICHAEL (1601-1660), German satirist, was born at Willstätt, near Strassburg, on the 5th of March 1601. He received a careful early education at the
MOSCHOPUS—MOSCOW 891

Latin School at Strassburg, and in 1620 began his academic career as a student of jurisprudence. After being for some years tutor in the family of the Graf von Leiningen-Dachsburg, he finally became privy councillor to the landgrave of Hesse-Cassel. He died at Worms on the 4th of April 1669. Under the name of "Der Traumende," Moscherosch was a member of the Fruchtbringende Gesellschaft, a society founded by Prince Ludwig of Anhalt-Cöthen, in 1671, for the purification of the German language and the fostering of German literature. His most famous work is the Wunderliche und wahrhaftige Geschichte Philandors von Sitterwald (anagram of Willstätt) (1642-1643), for which he took as his model the Suenos (visions) of the famous Spaniard Francisco Gomez de Quevedo y Villegas (1580-1645). Hardly inferior to the "visions" is the Insomnis cura parentum, Christliches Vermächtnis eines Vaters, which was published at Strassburg in 1643 and again in 1647. Noteworthy is also Die Patientia, discovered in 1897 in M.S. in the municipal library at Hamburg.

Selections from Moscherosch's writings have been published by W. Dittmar (1830), F. Boberius (in Kürschners Deutsche Nationalliteratur, xxx., 1884), and J. Müller (in Reclams Universalbiographien). Reprints of the Insomnis cura parentum and Patientia have been published by L. Pariser, published in 1887 and 1897, who is also the author of Beiträge zu einer Biographie von Moscherosch (1891). See also H. Schröder, Geschichte Moscherosch als Pädagogen (1885); and Wirth Moscherosch's Geschichte (1888).

MOSCHOPUS ("little calf," probably a nickname), MANUEL, Byzantine commentator and grammarian, lived during the end of the 13th and the beginning of the 14th century. The chief work is Ερωτηματα γραμματικα, in the form of question and answer, based upon an anonymous epitome of grammar, and supplemented by a lexicon (συλλογη) of Attic nouns. He was also the author of σχολια on the first and second books of the Iliad, on Hesiod, Theocritus, Pindar and other classic authors and latter authors; of riddles, letters, and a treatise on the magic squares. His grammatical treatises formed the foundation of the lavours of such promoters of classical studies as Manuel Chrysoloras, Theodorus Gaza, Guarini, and Constantine Lascaris.

A selection from his works under the title of Manuelis Moschopuli opuscula grammatica was published by F. N. Titze (Leipzig, 1822); see also C. Krummacher, Geschichte der byzantinischen Literatur (1897) and M. Treu, Maximi monachi Planudis epistolae (1890), p. 208.

MOSCHUS, Greek bucolic poet and friend of the Alexandrian grammatician Aristarchus, was born at Syracuse and flourished about 150 B.C. He was the author of a short epic poem, Europa, and a pretty little epigram, Λεον, the Runaway, imitated by Torquato Tasso and Ben Jonson. The epitaph on Bion of Smyrna, wrongly supposed to have been his tutor, was in all probability written about the time of Sulla (see F. Bücheler in Rheinisches Museum, xxx., 1873). The poem on Megara (the wife of Heracles) is probably not his, but a few other pieces, undoubtedly genuine, have been preserved. His poems are nearly all in hexameters. They are usually printed in editions of Bion and Theocritus, and are translated into many European languages.

The text has been edited by U. von Wilamowitz-Moellendorff, in the Oxford Scriptorum classicorum bibliotheca (1905); there are English translations by J. Banks in Bohn's Classical Library (1853), and by Andrew Lang (1886), together with Bion and Theocritus. See also F. Susemihl, Geschichte der griechischen Literatur in der Alexandrinerzeit. i. 231 (1891), and article Bion.

MOSCOW (Russian Moskva), a government of Central Russia, bounded by Russian governments of Tver on the N.W., Vladimir and Ryazan on the E., Tula and Kaluga on the S., and Smolensk on the W., and having an area of 12,855 sq. m. The surface is undulating, with broad depressions occupied by the rivers, and varies in elevation from 500 to 850 ft. The government is situated in the centre of the Moscow coal-basin, which extends into the neighbouring governments. Its geology has been carefully studied, and it appears that in the Tertiary period the surface of this province was already continental; but during the Cretaceous period it was to some extent overflowed by the sea. Jurassic deposits are represented by their upper divisions only; the lower ones, as well as Triassic and Permian deposits, are wanting. The Carboniferous deposits are of a deep-sea origin, and are only represented by the upper division which lies upon Devonian deposits, discovered in an arsiesion well at Moscow at a depth of 1,000 ft. The pendulum anomaly, mentioned by Kaspar Gottfried Schweitzer (1816-1873), has been investigated. It appears in a zone 10 m. wide and about 95 m. long from west to east, and is positive (+10-6") to the north of Moscow and negative (−2-7") to the south.

The government is drained by the Volga, which skirts it for a few miles on its northern boundary, by the navigable Sestra, which brings it into communication with the canals leading to St Petersburg, by the Oka, and by the Moskva. The Oka and Moskva from a remote period have been important channels of trade, and continue to be so notwithstanding the development of the railways. The Oka brings the government into water communication with the Volga. Extensive forests (39% of the entire area) still exist. The soil is somewhat unproductive; agriculture is carried on everywhere, but only two districts export corn, all the others being more or less dependent on extraneous supplies. The principal crops are rye, oats, barley, potatoes, with some flax, hemp and hops.

The population, 1,915,700 in 1873, numbered 2,430,540 in 1897, and 2,733,300 in 1917, and is largely composed of the Great Russians and belong to the Greek Church (4%, Nonconformists). The importance of the Moscow government as a manufacturing centre is steadily increasing, and it now stands first in Russia. The chief factories are for coppers, woollens, silks, clothing, chemicals, sugar refiners, distilleries, iron-works. There is besides a very great variety of minor industries—such as those concerned with gold thread and gold brocades, gold and silver jewelry, bronze, perfumery, sweets, tobacco, tanneries, gutta-percha, furniture, carriages, wall-paper, toys, baskets, lace, and papier-mâché. The government is divided into 13 districts.

The prehistoric archaeology of Moscow has been carefully studied. This district has been inhabited since the Stone Age. Bronze implements are rare, and there are places where instruments of stone, bone and iron are found together. The inhabitants who constructed the burial mounds in the 10th to 12th centuries seem to have been of Finnish origin, and were poorer, as a rule, than their contemporaries on the Volga.

MOSKOW, (Russian Moskwa), the second capital of the Russian empire, and chief town of the government of the same name, in 55° 45' N. and 37° 37' E., on both banks of the river Moskva, a tributary of the Volga. It is about 400 m. from St Petersburg, 1017 from Odessa, and 814 from Warsaw. It lies to the north of the most densely peopled parts of Russia (the "black-earth region"), whilst the country to the north of it is rather thinly populated as far as the Volga, and very sparsely beyond that. The space between the middle Oka and the Volga, however, was the cradle of the Great-Russian nationality (Novgorod and Pskov excluded); and four or five centuries ago Moscow had a quite central position with regard to that region.

The present city covers an area of 32 sq. m. (about 40 when the suburbs are included). In the centre, on the left bank of the Moskva, stands the Kreml or Kremlin, occupying the Borovitsky hill. To the east of the Kreml is the Kitay-Gorod, formerly the Great Posad, the chief centre of trade. The Byelyi-Gorod, which was formerly enclosed by a stone wall (whence the name), surrounds the Kremlin and the Kitay-Gorod on the west, north, and north-east. A line of boulevards now occupies the place of its wall (destroyed in the 18th century), and marks the first ring of streets round the centre of Moscow. The Zemlyanoy-Gorod (earthen enclosure) surrounds the Byelyi-Gorod, including the Zamoskvorechye on the right bank of the Moskva. The earthen wall and palisade that formerly enclosed it no longer exist, their place being taken by a series of broad streets with gardens on both sides—the Sadovaya, or Gardens Street. The fourth enclosure (the Kamer College earthen wall) was made during the reign of Catherine II.; it is of irregular shape, and encloses the outer parts of Moscow,
whilst the suburbs and the villages which have sprung up on the
highways extend some miles beyond.

The Kremlin is an old fort of pentagonal (nearly triangular)
shape, about 100 acres in extent, occupying a hill 130 ft. above
the level of the Moskva. It is enclosed by a high stone battle-
ment wall 2430 yds. in length, restored during the 19th
century, and having nineteen towers. Its five gates are sur-
mounted by towers and are all noteworthy. The Spaskiya
(Saviour's) Gate was erected in 1491 by a Milanese architect;
the Gothic tower (203 ft.) that surmounts it was added in 1626
by the English architect, Holloway. A sacred picture of the
Saviour (the "palladium of Moscow") was placed upon it in
1647, and all who pass through the gate uncover. The towers
surmounting the other four gates were erected by order of
Ivan III. Of the sacred buildings of the Kremlin the most
venerated is the Uspensky cathedral. The former church of
this name was erected in 1326 by the tsar, Ivan Kalita, but,
on its falling into disrepair, a new one was built on the former
place in 1475-1479, by the Bolognese architect, Fioraventi,
in the Lombardo-Byzantine style, with Indian cupolas. It was
restored each time after being pillaged or burnt in 1493, 1547,
1682 and 1812. It contains the oldest and most venerated
holy pictures in Russia, one of which is attributed to the metropo-
lian Peter, another to St Luke. The cathedral possesses
the throne of Vladimir I., and numerous relics of saints,
some of which date from the 14th century. The Russian
metropolitans and patriarchs were consecrated in this cathedral,
as well as the tsars after Ivan IV. The Arkhangel cathedral,
on the opposite side of the square, was originally built in 1333,
and a new one was erected in its place in 1505-1508. It contains
the tombs of the tsars from Ivan Kalita (1340) to Ivan Alexievich
(1666), and possesses vast wealth. The Blagoveschensk
cathedral, recalling the churches of Mount Athos (in Turkey),
was first built in 1397, rebuilt in 1484-1489, and restored in
1885. The remarkable pictures of Rubens (1474-1557) are still
preserved. It was the private chapel of the tsars, and in it
they are baptized and married. Vestiges of a very old church,
that of the Saviour, in wood, contemporaneous with the
foundation of Moscow, still exist in the yard of the palace.
A stone church took the place of the old wooden structure in 1339,
and was rebuilt in 1527. The Voznesensky convent, erected
in 1389-1393, and restored in the end of the 14th century, is
the burial-place of wives and sisters of the tsars. The Chudov
monastery, erected in 1358-1363 and rebuilt in 1771, was the
residence of the metropolitan of Moscow and a state prison.
Close by, the great campanile of Ivan Veliky, erected in
the Lombardo-Byzantine style by Boris Godunov, in 1609,
rises to the height of 277 ft. (83 ft. including the cross),
and contains many bells, one of which weighs 631 tons. Close by
is the well-known Tsar-Kolokol (king of the bells), 65 ft. in
circumference and the rim, 10 ft. high and weighing 1083 tons.
It was cast in 1735, and broken during the fire of 1737 before
being hung. The treasury of the patriarchs in the campanile
of Ivan Veliky contains not only such articles of value as the
sakkos (episcopal robes) of the metropolitans with 70,000 pearls,
but also very remarkable monuments of Russian archaeology.
The library has 500 Greek and 1000 very rare Russian MSS.,
including a Gospel of the 8th century.

The great palace of the tsars, erected in 1838-1849, is a fine
building in white stone with a gilded cupola. It contains the
terems, or rooms erected by Tsar Michael Fedorovich for
the young princes his sons in 1636 (restored in 1836-1849, their former
character being maintained), a remarkable memorial of the
domestic life of the tsars in the 17th century. In the treasury
of the tsars, in the Orujeynaya Palata, now public museums,
the richest treasures connected with old Russian archaeology are
preserved—crowns, thrones, dresses, various articles of house-
hold furniture belonging to the tsars, Russian and Mongolian
arms, carriages, &c. The Granovitaya Palata, another wing
of the great palace, consists of a single-vaulted apartment
built in 1473-1499, and is used as a state banqueting hall.
The four sides of the Senate Square are occupied by buildings
of various dates, from the 13th century onwards. Among them
is the imposing senate, now the law courts, erected by Catherine
II. (1771-1785). Facing it is the arsenal (1701-1706). The temple
of the Saviour, begun in 1817 in commemoration of the events
of the French campaign of 1812, was abandoned in 1827, and
a new one was built during 1838-1839 on a hill on the bank of
the Moskva, at a short distance from the Kremlin. Its style is
Lombardo-Byzantine, with modifications suggested by the
military taste of Nicholas I.

The Kitay-Gorod, which covers 121 acres, is the chief com-
ercial quarter of Moscow. It contains the new bazaars, a
triple block of buildings erected in 1888-1893 in sandstone,
at a cost of over £1,030,000, and the Gostinoy Dvor, consisting
of several stone buildings divided into 1200 shops. The Red
Square, 900 yds. long, with a stone tribunal in the middle,
which was formerly the forum, market cross and place of execu-
tion separates the bazaar from the Kremlin. At its lower
western end stands the historic Uspensky Cathedral (usually
known as Vasili Blazhennyi), one of the wonders of Moscow, on account
of its towers, all differing from each other and representing,
in their variety of colours, pine-apples, melons and the like.
It was begun by Ivan the Terrible in 1534 to commemorate the
conquest of Kazan, but not completed until 1679. It was
plundered and desecrated by the French in 1812, but restored
in 1830-1845. The exchange, built in 1838 and restored in 1873,
is very lively, and its "exchange artels" (associations of nearly
2000 brokers) are worthy of remark. Banks, houses of great
commercial firms, streets full of old book-shops carrying on a
very large trade, and finally the Tolkuchy rynek, the market
of the poorest dealers in old clothes, occupy the Kitay-Gorod,
side by side with restaurants of the highest class. In
this quarter are also situated the house of the Romanovs, the reigning
dynasty of Russia, rebuilt and refurnished in 1859 in exact
conformity with its former shape; and the printing-office of
the syndic of the Orthodox Greek Church, founded in 1521 and
containing about 600 MSS. and 10,000 very old printed books,
together with a typographical museum. At the entrance to
the Kitay-Gorod stands the chapel of the highly venerated
Virgin of lIberia, a copy made in 1648, of a holy picture placed
on the chief gate of the monastery of Mt Athos.

The northern parts of the Byelyi-Gorod are also the centre of
a lively trade. Here are situated the Okhotnyi Ryad (poultry
and game market) and the streets Tverskaya, Petrovka and
Kuznetsky-Most the rendezvous of the world of fashion. Here
also are the theatres, the industrial art museum, imperial bank
(1804), and Rozhdestvensky convent (founded in 1386). In
the south-west of the Byelyi-Gorod, opposite the Alexander Garden
on the west side of the Kremlin, stand the university (see below),
museum of domestic industries, Rumyantsev Museum and
church of the Redeemer. This last, built in the form of a Greek
cross in 1837-1838 at a cost of nearly £600,000, is dominated
by five gilded domes and faced externally with marble.
The interior is harmoniously decorated with gold and marble, and
adorned with pictures by Verestchagin and other Russian
artists. In the east of the city are three monasteries all dating
from the 14th century.

The Zemlyanoy-Gorod, which has arisen from villages that
surrounded Moscow, exhibits varied characteristics. In
the neighbourhood of the railway stations it has busy centres of
traffic; other parts are manufacturing quarters, whilst others—
for instance, the small quiet streets on the west of the boulevard
Prechistenka, called the old Konushennaya, with their wooden
houses and spacious courtyards—are the true abodes of the
families of the old, for the most part decayed, but still proud,
nobility. The Zamoskvorechye, on the right bank of the
Moskva, is the abode of the patriarchal merchant families.

The climate of Moscow is cold and continental, but healthy.
The average annual temperature is 40° F. (Jan., 14°;
July, 66°-75°). The summer is warm (64°-70°), and the winter
cold and dry (15°-20°), great masses of snow lying in the streets.
The spring, as is usually the case in cold continental climates,
is beautiful. The prevailing winds are south-west and south. 
The river Moskva is frozen, on the average, for 153 days (from Nov. 1 to April 13).

Moscow is crossed by five bridges; a branch of it, or rather a channel, makes an elongated island in the middle of the city. Water of excellent quality, principally from the Mytishchi springs and ponds, 11 m. distant, has since 1893 been led to fountains in different parts of the city, whence it is distributed by watermen.

The population was estimated at only 150,000 in the middle of the 18th century, and at 250,000 in 1812. Since 1870 it has been growing at the rate of about 2½ % per annum; (1872), 601,969; (1882), 753,469; (1902), 1,092,360, or including the suburbs 1,173,427; (est. 1907), 1,359,754. The housing problem is of great importance in Moscow, as it appears that over 10% of the domiciles are underground. And while the average for the city is two occupants to each room, there are more than 10,000 domiciles which have more than four occupants to each room, representing one-fourth of the population. The average mortality is consequently high, namely 28 per 1000 (33 per 1000 if the children inmates of the Foundling House be included).

Fires occur very frequently. The inhabitants are mostly Great-Russians. They belong chiefly to the Orthodox Greek Church, or to the Moscow (so-called) Reform Church; the Lutherans number 2% and the Roman Catholics 1%.

Since the 14th century Moscow has been an important commercial city. About the end of the 15th century its princes transported to Moscow, Vladimir, and other Russian towns no fewer than 18,000 of the richest Novgorod merchant families, and took over the entire trade of that city, entering into direct relations with Narva and Livonia. The annexation of Kazan (1552) and the conquest of Siberia (1580-1600) gave a new importance to Moscow, bringing it into direct commercial relations with Khiva, Bokhara and China, and supplying it with Siberian furs. The fur-trade had a great fascination for all European merchants in the 16th century, and an English company, having received the monopoly of the Archangel trade, caused their merchandise to be sent by the White Sea instead of by the Baltic. Moscow thus became the centre for nearly the entire trade of Russia, and the tsar himself engaged in large commercial operations. Situated at the intersection of six important highways, Moscow was the storehouse and exchange-market of the merchandise of Europe and Asia. The opening of the port at St Petersburg affected its commercial interest unfavourably at first; but the Asiatic trade and internal trade of Moscow have since then enormously increased. Here are concentrated the traffic in grain, in hemp and in oils sent to the Baltic ports; in tea, brought both by way of Siberia and of St Petersburg; in sugar, refined here in large quantities; in grocery wares for the supply of more than half Russia and all Siberia; in tallow, skins, wool, metals, timber, wooden wares, iron and steel goods, wine, drugs, raw cotton, silk and all other produce of the manufactures of middle Russia. As a railway centre the city plays so predominant a part that 1/4 to 1/3 of all the goods carried by the railways of European Russia are loaded or unloaded at Moscow. The banks, including the mortgage banks, are the most important in Russia.

From the 13th century onwards the villages around Moscow were renowned for the variety of small industries which they carried on; the first large manufactures in cloths, woollens, fabrics, silk, china and glass in Great-Russia were established at Moscow in the 17th and 18th centuries. After 1830, in consequence of protection tariffs, the manufactories in the government of Moscow rapidly increased in number; but two-thirds of them are now concentrated in the capital. Moscow is in fact the principal manufacturing city in the empire, employing about 100,000 operatives in her mills and factories. Nearly one-half of them are engaged in the textile industries, especially calico-printing. Next in importance comes the preparation of food-stuffs, followed by the metal and metallurgical industries and the chemical works.

Moscow has many educational institutions and scientific societies. The university, founded in 1755, exercised a powerful influence on the intellectual life of Russia during the years 1830-1848; and it still continues to be the most frequented Russian university. In 1904 it had over 5000 students, who are mostly poor. The library contains some 286,000 volumes, and has rich collections in mineralogy, geology and zoology. Among the museums the Rumyantsev, now connected with the so-called public museum, occupies the first rank. It contains a library of 700,000 volumes and 2300 MSS., remarkable collections of old pictures, sculptures and prints, as well as an extensive mineralogical collection, and an ethnographical collection representing very accurately the various races of Russia. The private museum of Prince Golitsin contains a good collection of paintings and MSS. The Shchukin Museum contains Russian antiquities, pictures and objects of industrial art. A number of excellent free libraries have been opened, two of them containing valuable collections of books and MSS. The remarkable Tretyakov gallery of pictures, chiefly of the Russian school, has been presented (1892) by its owner to the city. The philanthropic institutions include the vast foundling hospital (1764). The municipal relief of the poor was entirely reorganized in 1894, partly on the Elberfeld system and partly on quite new and original lines.

Moscow is surrounded by beautiful parks and picturesque suburbs. Of the former one of the most frequented is the Petrovsky Park, to the north-west, with a castle built in 1776, burnt by the French in 1812, but rebuilt in 1840. A little farther out is the Petrovskoye Razumovskoye estate, with an agricultural academy (1863) and its dependencies (botanical garden, experimental farm, &c.). Another large park and wood surround an imperial palace (1766) in the village of Ostankino. The private estates of Kuzminski, Kuskovo and Kuntsevo are also surrounded by parks; the last has remains of a very old graveyard, supposed to belong to the pagan period. In the south-west, on the right bank of the Moskva, which here makes a great loop to the south, are the Vorobeyovy hills, which are accessible by steamer from Moscow, and afford one of the best views of the capital. In the loop of the Moskva is situated the Novo-Dievichy or Virgins’ convent, erected in 1524 and connected with Sophia, sister of Peter the Great, and many events of Russian history. In the south, on the road to Serpukhov, is the site of Kolomna, founded in 1237, a favourite residence of Ivan the Terrible and Peter the Great, with a church built in 1537, a striking monument of Russian architecture, restored in 1880. The monastery Nikoloi-Ugryeshsky, 12 m. from the city, between the Kursk and Ryazan railways, occupies a beautiful site and is much visited by Moscow merchants, to venerate a holy picture by which Dmitry Donskoi is said to have been blessed before going to fight (1380) the Mongols. In the north, the forest of Sokolniki, covering 45 sq. m., with its radial avenues and numerous summer residences, is the part of Moscow most frequented by the middle classes.

History. The Russian annals first mention Moscow in 1147 as a place where Yury Dolgoruki, prince of Suzdal, met Svyatoslav of Syeversk and his allies. The site was inhabited from a very remote antiquity by the Merya and Mordvinians, whose remains are numerous in the neighbourhood, and it was well peopled by Great-Russians in the 12th century. To the end of the 13th century Moscow remained a dependency of the princes of Vladimir, and suffered from the raids of the Mongols, who burned and plundered it in 1237 and 1293. Under Daniel, son of Alexander Nevsky (1261-1302), the prince of Moscow first acquired importance for the part he took in the wars against the Lithuanians. He annexed to his principality Kolomna, situated at the confluence of the Moskva with the Oka. His son in 1302 annexed Pereyaslavl Zalesky, and in the following year Mozhaisk (thus taking possession of the Moskva from its source to its mouth), and so inaugurated a policy which lasted for centuries, and consisted in the annexation by purchase and other means of the neighbouring towns and villages. In 1300 the Kremlin, or fort, was enclosed by a strong wall of earth and timber, offering a protection to numerous emigrants from the
Tver and Ryazan principalities. Under Ivan Kalita (1325-1341) the principality of Vladimir—where the princes of Kiev and the metropolitan of Russia had taken refuge after the wars that desolated south-eastern Russia—became united with Moscow; and in 1325 the metropolitan Peter established his seat at Moscow, thus giving new importance and powerful support to the young principality. In 1357 the Kremlin was enclosed within stone walls, which proved strong enough to resist the Lithuanians under Olgiard (1368 and 1371). Kalita’s grandson, Dmitry Donskoi, annexed the dominions of Starodub and Rostov, and took part in the renowned battle of Kulikovo (1380), on the Don in the government of Tula, where the Russians ventured for the first time to oppose the Mongols in a great pitched battle. Two years after the battle of Kulikovo Moscow was taken and plundered (for the last time) by Toktamish, khan of the Golden Horde of the Mongols.

The increase of the principality continued during the first half of the 15th century, and at the death of Vasili (or Basil) the Blind, in 1462, it included not only the whole of what is now the government of Moscow, but also large parts of the present governments of Kaluga, Tula, Vladimir, Nijniy-Novgorod, Kostroma, Vyatka, Vologda, Yaroslav and Tver. It was not however until the reign (1462-1505) of Ivan III that the whole of the Russian country within the city, known as the terest, was added to the principality of Moscow, and called himself “Ruler of all Russia.” In 1530 Moscow was said to contain 45,000 houses and 100,000 inhabitants. Ivan IV, annexed Novgorod and Pskov to Moscow, and subdued Kazan and Astrakhan. But after his reign Moscow suffered from a long series of misfortunes. In 1547 two conflagrations destroyed nearly the whole of the city, and a few days later the Tartar khan of the Crimea advanced against it with 100,000 men. He was compelled to retire from the banks of the Oka, but in 1571, taking advantage of the state into which Russia was brought by the extravagances of Ivan, he took Moscow and burned all the city outside the Kremlin. The gates of the Kremlin having been shut, thousands of people perished in the flames, and the annals record that of the 200,000 who then formed the population of Moscow, only 30,000 remained. In 1591 the Tartars of the Crimea were again in Moscow and avenged their repulse from the Kremlin on the inhabitants of the fortunated town. Meanwhile the political influence of the boyars had gradually increased. The peasants, who settled on their lands, or on the estates which the prince bestowed upon his boyars, had gradually become less dependent on the tsar, and assumed more and more, especially under Alexis Mikhailovich (1645-1666), the character of a private estate of the tsar, its suburbs becoming mere dependencies of his vast household.

During the whole of the 17th century Moscow continued to be the scene of many troubles and internal struggles. The people several times revolted against the favourites of the tsar, and were subdued only by cruel executions, in which the streltsy—a class of citizens and merchants rendering hereditary military service—supported the tsar. Afterwards appeared the raspol or nonconformist movement, and in 1648, when the news spread that Stenka Razin was advancing on Moscow “to settle his accounts with the boyars,” the populace was kept from rising only by severe repressive measures and by the defeat of the invader. Later on, the streltsy themselves engaged in a series of rebellions, which led the youthful Peter the Great to suppress them (1698) amid streams of blood. The opposition encountered at Moscow to his plans of reforming Russia according to his ideal of military autocracy, the conspiracies of the boyars and merchants, the distrust of the mass of the people, all compelled him afterwards to leave (1703) the city, and to seek, as his ancestors had done, a new capital. This he founded at St. Petersburg on the very confines of the military empire he was trying to establish.

In the course of the 18th century Moscow became the seat of a passive and discontented opposition to the St Petersburg government. Peter the Great, wishing to see Moscow like other capitals of Western Europe, ordered that only stone houses should be built within the walls of the town, that the streets should be paved, and so on; but his orders were only partially executed. In 1722 the Kremlin was restored. In 1730 the appointment of a French architect caused riot and rebellion; some others followed in 1748 and 1753, and gave an opportunity for enlarging some streets and squares. Catherine II. tried to conciliate the nobility, and applied herself to benefit the capital with new and useful buildings, such as the senate house, the foundlings’ and several other hospitals, salt stores, &c.

The last public disaster was experienced by Moscow in 1812. On the 13th of September, six days after the battle of Borodino, the Russians troops evacuated Moscow, and the next day the French occupied the Kremlin. The same night, while Napoleon was waiting for a deputation of Moscow notables, and received only a deputation of the rich raspolnich merchants, the capital was set on fire through the carelessness of its own inhabitants (it was no heroic deed of Rostophin’s), the bazaar, with its stores of wine, spirits and chemical stuffs, becoming the prey of the flames. The inhabitants abandoned the city, and it was pillaged by the French troops, as well as by Russians themselves, and the burning of Moscow became the signal of a general rising of the peasants against the French. The want of supplies and the impossibility of wintering on a settled basis compelled Napoleon to leave Moscow on the 19th of October, after he had unsuccessfully attempted to blow up certain parts of the Kremlin.

MOSEL (Fr. Moselle), a river of France and Germany, a left-bank tributary of the Rhine. It rises at an altitude of 2411 ft. on the west flank of the Vosges, close to the Franco-German frontier, and a little N. of the Ballon d’Alsace. It flows first N.W. through the French department of Vosges, bends towards N. through that of Meurthe-et-Moselle, forms the Franco-German frontier for a short distance below Pagny, and enters Lorraine. From Sierck to Wasserbillig it forms the frontier between the Rhine Province and Luxembourg, then, turning N.E., it follows a sinuous course and reaches the Rhine at Coblenz. The principal towns on the banks of the Mosel are, in France: Remiremont, Épinal, Toul and Pont-à-Mousson; in Germany: Metz, Diedenhofen, Trier (Trèves) and Coblenz. The Mosel receives the waters of the Moselotte, Meurthe, Seille and Saar (its principal tributary) on the right, and the Madon, Orne and Saulx on the left. Navigation for small vessels extends downwards from Frondard, a little below Nancy, the Mosel canal affording communication from a point above Metz to the frontier. In the lower part of the valley are the vineyards from which the well-known Mosel wines are produced. The valley of the Mosel, especially the part between Trier and Kochen, is noted both for picturesque scenery and for many sites of antiquarian interest. The length of the river is 314 m.

MOSELLE-LINE, the designation of a line of French barrier forts (forts d’arrêt) on the upper Moselle between the fortresses.
of Épinal and Belfort (see these articles, also MEUSE LINE and articles referred to therein). The purpose of this line, the separate forts of which command the relatively few lines of advance from upper Alsace through the Voges, is to deflect a possible German invasion from Alsace either towards Belfort or towards the open gap between Épinal and Toul called the Troué d'Épinal.

MOSEN,—MOSES

895

The (See land der to and at but letzten Bernhard articles of 1842), publicist, possible connexion this account, to the Epinal collection Ritter Schmid, new deutsches Zehn (1838), which was followed by a new collection of short stories (Bilder im Roose, 1846). In 1844 Mosen accepted the appointment of dramaturge at the Court Theatre in Oldenburg, but he was soon afterwards stricken with paralysis, and after remaining an invalid for many years, died at Oldenburg on the 10th of October 1867. Of his later works may be mentioned Die Dresdner Gemäldegalerie (1844), and the tragedies Herzog Bernhard (1853) and Der Sohn des Fürsten (1858).

A collection of his works, Sämtliche Werke, appeared in 8 vols. (1863; new ed., by his son, with a biography; 6 vols., 1880).

MOSER, JOHANN JAKOB (1701-1785), German jurist, was born at Stuttgart on the 18th of January 1701. He studied at the university of Tübingen, where, at the early age of nineteen, he was appointed extraordinary professor of law. In 1729 he became ordinary professor, and in 1736 he accepted a chair and directorship in the university of Frankfurt-on-the-Oder. On account, however, of differences with King Frederick William I. of Prussia, he resigned these offices in 1739 and retired to Ebersdorf, a village in the principality of Reuss, where for several years he devoted himself wholly to study, and especially to the production of his Deutsches Staatsrecht. In 1751 he was recalled to Württemberg as district counsellor, and in 1759 was imprisoned at Hohenwiel on account of the steps he had taken in connexion with this office against certain tyrannical proceedings of the duke. In 1764 he received his liberty and was restored to office. He died on the 30th of September 1785. Moser was the first to discuss in an adequate form the subject of European international law. He wrote more than 500 volumes, his principal works being Deutsches Staatsrecht (1737-1754), Neues deutsches Staatsrecht (1760-1775), Deutsches Staatsarchiv (1751-1757), Grundriss der heutigen Staatsverfassung von Deutschland (1754).

MÖSER, JUSTUS (1720-1794), German publicist and statesman, was born at Osnabrück on the 14th of December, 1720. Having studied jurisprudence at the universities of Jena and Göttingen, he settled in his native town as a lawyer. The confidence he inspired among his fellow citizens soon led to his being appointed advocatus patriae (state attorney). On the appointment of the duke of York (son of George III. of England) to the lay Protestant bishopric of Osnabrück, he was attached to the person of the new ruler as legal adviser, and continued in this office of trust for twenty years. From 1762 to 1768 he was justiciarius (chief justice) of the criminal court in Osnabrück; and in 1768 was made Geheimer Referendar (private councillor of justice). He died at Osnabrück on the 8th of January 1794. Not only as a statesman and administrator, but also as a publicist, Moser occupied a leading position among the men of his time. His history of Osnabrück (1768; 2nd ed. 1780; 3rd ed. 1810) is a masterly work. In his Patriotische Phantasien (1775-1786; 2nd ed. by his daughter, I. W. J. von Voigtz, 1804; new ed. by R. Zöller, 1871) he shows himself in advance of his times, pleading as he does for a national organic development of a state in the place of arbitrary laws imposed by the sovereign. His Vermissiche Schriften (published by F. Nicolai with a biography, 1757-1768) also display a deep insight into human nature and sparkle with humour and witty sallies. Moser was also a poet of some repute and wrote a tragedy, Arminius (1749). A statue of him by Drake was unveiled in Osnabrück in 1836.

His collected works, Sämtliche Werke, were published by B. R. Abeken (10 vols., 1842-1844). See J. Kreysig, Justus Moser (1830); K. Rüpprecht, Justus Moser's sociale und sozialwissenschaftlichen Anschauungen (1892); K. Mollenhauer, Moser's Antrieb an der Wiederbelebung des deutschen Geistes (1896).

MOSES (Gr. Μωϋσῆς, Moisēs), the great Jewish lawgiver, prophet and mediator, and leader of the Israelites from Egypt to the eastern borders of the promised land. The records of his life and work are noticed in the articles EXODUS, NUMBERS, DEUTERONOMY, where the several sources of the narratives are described. He appears in Midian at the “Mount of God” (Horeb) dwelling with its priest Jethro (q.v.), one of whose seven daughters he married, thus becoming the father of Gershom and Eliezer. Of his earlier life it was said that he was born in Egypt, in the Levite parentage, and when the Pharaoh commanded that every new-born male child of the Hebrews should be killed, he was put into a chest and cast upon the Nile. He was found by Pharaoh’s daughter, and his (step-)sister Miriam convinced that he should be nursed by his mother; on growing up he killed an Egyptian who was oppressing an Israelite, and this becoming known, he sought refuge in flight.

The story of the youth of Moses is, as is commonly the case with great heroes, of secondary origin; moreover, the circumstances of his birth as related in Exod. ii. find numerous parallels in legend elsewhere, e.g. in the story of the historical Sargon (L. W. King, Early Bab. Kings, ii. 87 sqq.), in the myths of Osiris and many others (see, at length, A. Jeremias’s Das Alte Test. im Lichte des alten Orientis, 1906, pp. 406 sqq.; Bab. im N. Test. p. 30 seq.). The story of the adoption of Moses by the Egyptian princess appealed to later imagination (Josephus, Ant. ii. 9, 10; Acts vii. 20-22), and many fanciful fables grew up around this and the other biblical statements. The name Mōshe, explained by the fact that the princess “drew him” (mōšāḏ) out of the waters, means properly “one who draws”, a derivation from Eg. mēš(ā), “child”, finds more favour, but is not certain.

At the holy mount, Moses received the divine revelation and was commissioned to bring the people a three-days’ journey out of Egypt to sacrifice at this spot (Exod. iii. 12, 18; v. 3; viii. 27). The deity revealed himself in a new name, Yahweh, with signs and wonders fortified Moses for his task. On his return he experienced a remarkable incident which is obscurely associated with the rite of circumcision.1 The plagues with which the reluctant Pharaoh was coerced culminated in the destruction of all the first-born, and Israel escaped to the Red Sea. The pursuing Egyptians were drowned, and the miraculous preservation of the chosen people at the critical moment marks the first stage in the national history.2 (See Exodus, Titr.)

1 The other events need not be detailed. Kadesh (holy) was Exod. iv. 24-26; it possibly explains the transference of the rite from ancient Egypt to the new-born son. For a recent discussion, see H. P. Smith, Journ. Bib. Lit. (1906), pp. 14-24; and the article CIRCUMCISION (with J. G. Frazer’s essay in the Independent Review 1904, pp. 204-218).

2 The plagues appear to have been amplified. In Exod. iv. three signs are given: the hand of Moses is stricken with leprosy and restored (the sign for Moses); his rod becomes a serpent (cf. vili. 8-13, the sign for Pharaoh); and the water is turned into blood (cf. vii. 17). Subsequent to the Pharaoh’s last refusal the first-born is threatened (iv. 21 sqq.). As regards the crossing of the Red Sea, a perfectly rationalizing explanation can be found: with a strong east wind its waters could temporarily recede and permit a passage (see Journ. Inst. xxvi. 28; xxviii. 268, 277). To the Israelites, however, it was a miracle, an unexpected intervention on the part of Yahweh, and the first of many marvels which he performed on behalf of the people of his choice. To rationalize this or any of the series misses the whole point of the religious history.
the chief centre. This was the scene of the "strife" at Meribah (striving) where Yahweh "shewed himself holy" (Num. xxi. 1-3); a parallel account joins the name with Massah (trial, proof) where Yahweh "proved" the people (Exod. xvii. 1-7). These two names (Deut. ix. 22, xxxii. 51) with their significant meanings recur with varying nuances (I. Kings. vii. 18, xv. 8 seq.). Here also in the wilderness of Shur, and possibly at En-mishpat (well of judgment, i.e. Kadesh, Gen. xiv. 7), Yahweh made for Israel "statute and judgment" and "proved them." This is apparently viewed as the goal of the three-days' journey (Exod. xv. 22-25). In this district the defeat of the Amalekites is more naturally located (Exod. xvi.; cf. I Sam. xxvii. 8) and here, finally, for some cause, now obscured, Moses and his brother Aaron (q.v.) incurred Yahweh's displeasure (Num. xxii. 12, xvii. 14; Deut. xxxii. 51; Ps. cv. 3). Pisgah or Mt Nebo (the name suggests a foreign god), to the north-east of the Dead Sea became the scene of the death of Moses; his burial-place was never known (Deut. xxxiv.).

In estimating the work of one who stands at the head of the religious and legal institutions of Israel, it is necessary to refrain from interpreting the traditions from a modern legal standpoint or in the light of subsequent ideas and beliefs for which the sources themselves give no authority. Much confusion has been caused by attributing to Moses more than the Pentateuch itself claims, and by misunderstanding the meaning of later references (Mat. xix. 8; Mark vii. 10, x. 5; xii. 26; Luke xx. 37; John vii. 22). Moreover, it is necessary to allow that the traditions relating to both Moses and Aaron underwent change. The priesthoods of Shiloh and Dan could boast of an illustrious origin (I Sam. ii. 27 seq., Judges xviii. 30), but the religious practices associated with the former especially were not those of the purest type. When Aaron himself is connected with the worship of the golden calf, and when Moses is attributed a brazen serpent which the reforming king Hezekiah was the first to destroy, it is evident that religious conceptions developed in the course of ages. Although Moses was venerated as a prophet (Ios. xii. 13), a mediator (Jer. xv. 1) and a leader (Mic. vi. 4; Isa. xliii. 11), much of the legal procedure ascribed to him must belong on internal grounds (religious, ethical and sociological evidence) to a post-Mosaic age. Many of the Mosaic laws find parallels and analogies in all ages outside the sphere of Israelite influence, notably in the laws codified several centuries previously by the Babylonian king Khammurabi (see BABYLONIAN LAW). The practice of finding in ancient authority a precedent for institutions new and old (cf. the law of booty, I Sam. xxx. 25, with that ascribed to Moses in Num. xxxi. 25 seq.) is quite in accordance with Oriental custom and explains the growth of the present extremely complex sources. But this very development of Mosaicism implies the existence of an original nucleus or substratum, although the recovery of its precise extent is very difficult. The legislation on Mt Sinai (Horeb) which apparently occupies a very important place in tradition (Exod. xx. seq.) is really secondary (cf. W. R. Smith, Prophecies of Israel, p. 111); more prominence is evidently to be ascribed to the traditions of Jethro or Hobah, and this must be taken into consideration with what is known of Kenite and kindred clans (Exod. xviii.; Num. x. 29-33; see JETHRO; KENITES). Yahweh appears to have been known to them before he revealed himself to Moses, and the ancestors of the Israelites are recognized as worshippers of Yahweh, but are on another level (Exod. vi. 3). The traditions would seem to point to the institution of new principles in the religion of Yahweh, and would associate with it not merely Moses but those foreign elements which are subsequently found in Israel and Judah. See JEW, §§ 5, 14, 20.

1 See K. Budde, Religion of Israel to the Exile, ch. 1. According to Gen. iv. 26, so far from the name Yahweh having been made known to Israel by Moses (Exod. iii. 13 seq., vi. 2 sqq.), the worship goes back to the earliest ages.

The Greek Text of the Hebrew Bible is the produced by the Greek translation of the Hebrew text, known as the Septuagint (LXX). The text was produced by skilled translators and was intended for a Greek-speaking audience. The text of the Greek version is generally considered to be the most reliable and accurate of all the old versions of the Hebrew Bible, and it is considered to be the standard text for the Greek translation of the Hebrew Bible. The Greek text of the Hebrew Bible is the most widely used text in the Greek-speaking world, and it is the text used in most modern versions of the Bible, including the King James Version of 1611. For more information, see the article "Greek Text of the Hebrew Bible."
MOSES OF CHORENE

idiotic phrases survive in the text. Thus circumscribunt (11. 7) = "I will protect," i.e., ΜΕ (cf. Deut. xxxii. 10), and in sacerdotes vocabatur = als leps φυλακαρει, κυρ. υπερ βαφ. (cf. 1 Chron. xxiii. 14, and Is. xlviii. 2), = "they will call themselves priests." (2) Frequently it is suggestive of the original Testament is preserved in the Latin version and it is probable that some corruptions in the text. (3) In some cases we must translate not the Latin but the Hebrew presupposed by it. Thus in i. 7, successor = δομινος = μυρό, must be rendered "minister." 

Testament of Moses.—The present book is possibly the long lost Testamentus Mose and mentioned in some of the ancient lists, for it never speaks of the Messiah, but always of his natural death (i. 12, ii. 13, x. 14). About a half of the original Testament is preserved in the Latin version, and the fragments probably deal with questions about the Creation (see Fabric. Cod. pseud. V. T., ii. 844: Acta synodi Niceanae, ii. 20). With this Testament the Assumption, to which almost all the patristic references and the like have been made, was subsequently edited.

Someviews of Author.—Our author's views on Moses are remarkable. He writes that Moses was prepared from before the foundation of the world to be the mediator of God's covenant with his people (xi. 9). Apparently his relation to Israel did not cease with death, as he was to be his intercessor in the spiritual world (xii. 6). His death was an ordinary one (i. 12, iii. 12, x. 14), but no single place was worthy to mark the place of his burial, for his sepulchre was from the rising to the setting sun, and from the sea to sea, which would be noted by the whole world (xi. 8). On the doctrine of good works our author's views are allied to Old Testament conceptions rather than to the rabbinic doctrine of man's righteousness, which bulks so largely in Jewish literature, and in this, towards a national hero's righteousness as involving merit over against God, our author represents the greatest hero of Israel as declaring "Not for any virtue or strength of mine, but in His compassion and suffering we are saved." (xii. 17.)

Literature.—Editions of the Latin text: Ceriani Monumenta sacra et profana, I. i. 55-64 (1861); Hilgenfeld, Nova test. extra can nonem recept. 107-135 (1867); Volkmann, Moses Prophet and Historian (1867); Schmid and Meurer, Die Annalengeschichte von Mose (1868); Charles, The Assumption of Moses (translation, with notes and introduction, 1897); Kuenen, in Kautzsch's Apoc. and Paral., ii. 311-332.

Josephus (xi. 9).—For the full account of these see Schürer, ii. 222; Charles op. cit. xxi-xxviii. (R. H. C.)

MOSES OF CHORENE, Armenian historian, was a native of Khorin't in Taron, a district of the Armenian province of Turum. According to the History of Armenia which bears his name he was a pupil of the two fathers of Armenian literature, the patriarch or catholicos Sahak the Great and the vartabed Mesrobag. Shortly after 410 he was sent by these men to Alexandria to study the Greek language and literature, and thus prepare himself for the task of translating Greek writings into Armenian. Moses took his journey by Edessa and the sacred places of Palestine. After finishing his studies in the Egyptian capital he set sail for Greece; but the ship was driven by contrary winds to Italy, and he seized the opportunity of paying a flying visit to Rome. He then visited Athens, and, towards the end of winter (410) arrived in Constantinople, whence he set out on his homeward journey. On his arrival in Armenia he found that his patrons were both dead. The History of Armenia speaks of its author as an old, infirm man, constantly engaged in the work of translating. In the later Armenian tradition we find other notices of this celebrated man—one such, that he was the nephew of Mesrobag, that he was publicly complimented by the emperor Marcian, that he had been ordained bishop of Bagaward by the patriarch Gintik, and that he was buried in the church of the Apostolic Cloister at Mush in the district of Taron; but these accounts must be received with great caution. This remark applies especially to the statement of Thomas Ardashuni, that Moses, like his Hebrew prototype, lived to the age of 120 years, and recorded his own death in a fourth book of his great work. The same statement was extended to another tradition, based on an arbitrary construction of a passage in Samuel of Ani, which places his death in the year 489.

The History of Armenia, or, as the more exact title runs, the

Collectors of the Latin text of the History of Armenia, ii. 47.

In Broustet, Collection d'histoire armenniens, i. 68.

The oldest MS. is that of St. Lazarus of the 12th century. Colla-

Genealogical Account of Great Armenia, consists of three books, and reaches down to the death of Saint Mesrob, in the second year of Yazgedgird II. (Feb. 17, 440). It is dedicated to Sahak Bagratuni (who was afterwards chosen to lead the revolting Armenians in the year 481), as the man under whose auspices the work had been undertaken. This work, which in course of time acquired canonical authority among the Armenians, is partly compiled from sources which we yet possess, viz., the Life of Saint Gregory by Agathangelas, the Armenian translation of the Syriac Doctrine of the Apostles Addai, the Antiquities and the Jewish War of Josephus, and above all the History of Mar Abas Katina (still preserved in the extract from the book of Sefos), who, however, did not write, as Moses alleges, in Syriac and Greek, at Nisibis, about 131 B.C., but was a native of Medesburg, and wrote in Syriac alone about A.D. 383, or shortly thereafter. Besides these, Moses refers to a whole array of Greek authorities, which were known to him from his constant use of Eusebius, but which he has not been able to relate all that he makes them relate. Although Moses assures us that he is going to rely entirely upon Greek authors, the contents of his work show that it is mainly drawn from native sources. He is chiefly indebted to the popular ballads and legends of Armenia, and it is to the use of such materials that the work owes its permanent value. Its importance for the history of religion and mythology is, in truth, very considerable, a fact which it is the great merit of Emin9 and Dulongier8 to have first pointed out. For political history, on the other hand, it is of much less value than was formerly assumed. In particular, it is not a history of the people or of the country, but a history of the Armenian aristocracy, and, in opposition to the Mâkonian tendency which pervades the rest of the older Armenian historical literature, it is written in the interest of the rival Bagratunians. Down to the 3rd century it is further proved by the contemporary Graeco-Roman annals to be utterly unfounded in fact. At the time of Armenian Christianity it must be used far more cautiously than it has been done, for example, by Gibbon. The worst feature is the confusion in the chronology, which, strange to say, is most hopeless in treating of the contemporaries of Moses himself. What can be thought of a writer who assigns to Yazgedgird I. (309-420) the eleven years of his predecessor Bahram IV., and the twenty-one years of Yazgedgird I. to his successor Bahram V. (420-439)? A. von Gutschmidt9 at one time attempted to explain this unhistorical character of the narrative from a tendency arising out of the peculiar ecclesiastical and political circumstances of Armenia, situated as it was between the eastern Roman and the Persian empires, circumstances which were substantially the same in the 5th as they were in the two following centuries. In the course of further investigations, however, he came to the conclusion that, besides the many false statements which Moses of Khoren makes about his authorities, he gives a false account of himself. That is to say, the author of the History of Armenia is not the venerable translator of the 5th century, but some Armenian writing under his name during the years between 634 and 642. The proof is furnished on the one hand by the geographical and ethnographical nomenclature of a later period of MSS. of Etchmiadzin and Jerusalem are given by Agop Garinian, Tiflis (1858), 400. The book has been edited and translated by Whiston (London, 1736, 400); and by Le Valliant de Florival (Veyrier, Paris, 1911). The work was, however, edited and published. The commencement of this king's reign has been fixed by Noldke (Geschichte der Sassaniden aus Tabari, p. 432) as 4th August 438; and this date has been subsequently established by documentary evidence from the fact of the martyrdom of Pethon (see Hoffmann, Auszüge aus syrischen Akten persischer Mâtyrzer, p. 67).

Translated in Langlais, i. 105 seq.

1 The following statements, the evidence may be found in the article "Ueber die Glaubwürdigkeit der Armenischen Geschichte des Moses von Khoren," by Alfred von Gutschmidt, in the Berichte der phil. hist. Classe der könig. thä. Gesellschaft der Wissenschaften zu Göttingen, 1859.

2 The Epic Songs of Ancient Armenia (Arm.) (Moscow, 1850).

4 "Ueber die Glaubwürdigkeit," &c., p. 8 seq.

XVIII. 29
and similar anachronisms, which run through the whole book and are often closely incorporated with the narrative itself, and on the other hand by the identity of the author of the History, with that of Geography, a point on which all doubt is excluded by a number of individual affinities, not to speak of the similarity in geographical terminology. The critical decision as to the authorship of the Geography must settle the question for the History also.

The Geography is a meagre sketch, based mainly on the Chorography of Pappus of Alexandria (in the end of the 4th century), and indirectly on the work of Ptolemy. Only Armenia, the Persian Empire, and the neighbouring regions of the East are independently described from local information, and on these sections the value of the little work depends. Since the first published text contains names like "Russians" and "Criman", Saint Martin in his edition denied that it was written by Moses, and assigned its origin to the 10th century. It was shown, however, by L. Indjijian that these are interpolations, which are not found in better manuscripts. And in fact it is quite evident that a book which gives the division of the Sassanid Empire into four shapshabes in pure old Persian names cannot possibly have been composed at a long interval after the time of the Sassanidae. But of course it is equally clear that such a book cannot be a genuine work of Moses of Khora'n; for that division of the empire dates from the early part of the reign of King Chosroes I. (531-579). Accordingly K. P. Patkanov, to whom we are indebted for the best text of the Geography, is of opinion that we have it in a writing of the 7th century. If the limits within which the Geography was composed are to be more nearly defined, we may say that, from isolated traces of Arab rule (which in Armenia dates from 651), it must have been written certainly after that year, and perhaps about the year 673.

The extant work of Moses is a Manual of Rhetoric, in ten books, dedicated to his pupil Theodorus. It is drawn up after Greek models, in the taste of the rhetoric and sophistry of the later imperial period. The examples are taken from Hemonides, Theon, Aphthonius, and Libanius; although the author is also acquainted with lost writings—e.g., the Pelidæ of Euripides. On account of the divergence of its style from that of the History of Armenia, Armenian scholars have hesitated to ascribe the Rhetoric to Moses of Khora'n; but, from what has been said above, this is rather to be regarded as a proof of its authenticity.

Smaller works bearing the same honoured name are—the Instance of the Sacred Arderunt; the History of the Holy Mother of God and Her Image (in the cloister of Hogotsvanch in the district Andzevati of the province of Vaspurakan), which is also addressed by Saukerb and the Panegyric on Saint Khosrow. Of the several poems attributed to him, there is only one short prayer, contained in the hymnal of Sharakan, which can really claim him as its author.

Of works passing under the name of Moses of Khora'n, the following are regarded by the historians of Armenian literature as spurious: a History (distinct from the Panegyric) of the wanderings of Saint Khosrop and his Companions; A Homily on the Transfiguration of Christ; a Discourse on Wisdom (i.e., the science of grammar); the Commentaries on Grammar (an exposition of Dionysius Thrax). In the case of the grammatical writings, it has been suggested that there may have been some confusion between Moses of Khora'n and a Moses of Slunich, who lived in the 7th century.

Literature.—The date of the History of Moses has been discussed in many monographs. See especially the brochure of A. Carrière, Nouvelles sources de Moïse de Khoren (Vienna, 1893), who sets it in the 8th century. A Russian critic, I. Kholateants, arrives at a similar conclusion in his Armtians'k月份 (Moscow, 1899), F. C. Conybeare, in an article on "The Date of Moses of Khoren," in the Byzantinische Zeitschrift, vol. xi., and in a second in vol. ii., entitled "The Relation of the Paschalian Chronicle to Malalas," challenges Professor Carrière's arguments, and contends that the History of Moses is a late 5th-century work, much interpolated in its intermediate recensions. (A. V. G.; F. C. C.)

MOSHEIM, JOHANN LORENZ VON (c. 1604-1755), German Lutheran divine and Church historian, was born at Lübeck on the 9th of October, 1605. After studying at the gymnasium of his native place, he entered the university of Kiel (1716), where he took his master's degree in 1718. In 1719 he became assessor in the philosophical faculty at Kiel. His first appearance in the field of literature was in a polemical tract against John Toland, Vindiciae antiquae christianorum disciplinae (1720), which was soon followed by a volume of Observationes sacrae (1721). These works, along with the reputation he had acquired as a lecturer and preacher, secured for him a call to Helmstädt as professor ordinarius in 1723. The Institutionum historiarum ecclesiasticarum libri IV. appeared in 1726, and in the same year he was appointed by the duke of Brunswick abbott of Marienthal, to which dignity and emolument the abbacy of Michaelstein was added in the following year. Mosheim was much consulted by the authorities when the new university of Göttingen was being formed; especially in framing the statutes of the theological faculty, and the revisions for making the Geologik independent of the ecclesiastical courts. In 1747 he was made chancellor of the university. He died at Göttingen on the 9th of September. Among his other works were De rebus christianorum ante Constantinum commentarius (1753), Ketzer-Geschichte (2nd ed. 1748), and Sittenlehre der heiligen Schrift (1735-53). His exegetical writings, characterized by learning and good sense, include Cognitiones in N. T. loc. select. (1726), and expositions of 1 Cor. (1741) and the two Epistles to Timothy (1755). In his sermons (Heilige Reden) considerable eloquence is shown, and a mastery of style which justifies the position he held as president of the German Society.

There are two English versions of the Institutiones of Archibald Medcalf Murdoch, published in 1876, and that of James Murdock (1832), which is the more correct. Murdock's translation was revised and re-edited by James Seaton Reid in 1848, and by H. L. Hastings in 1892 (Boston). An English translation of De rebus christianorum was published by Murdock in 1851.

MOSLER, HENRY (1841-), American artist, was born at New York, on the 6th of June 1841, the family removing to Cincinnati when he was about ten years old. Studying drawing by himself, he became a draughtsman for a comic paper, the Omega (Boston), in 1855; in 1855-1856 he was a student at the Art Academy, and in 1857 he was in Paris during the Civil War, was an art correspondent of Harper's Weekly. In 1863 he went to Düsseldorf, where for almost three years he was at the Royal Academy schools; he subsequently went to Paris, where he studied for a short time under Ernest Hébert. His "Le Retour,"
from the Paris Salon of 1879, was the first American picture ever bought for the Luxembourg. He received a silver medal in Paris 1889, and gold medals at Paris, 1888, and Vienna, 1893. Examples of his work are in the Sydney Art Museum, N.S.W., and the art museums of Springfield, Mass., Cincinnati, Ohio and New York. His son, Gustave Henry Moseley (1875-1906), a pupil of his father and of Léon Bonnat, exhibited at the Salon in Paris, receiving a medal for his "De Profundis" in 1901; his portrait of Governor J. W. Stewart is in the State House, Montpelier, Vermont, and his "Empty Cradle" is in the Toledo Art Club.

MOSQUE (through Fr. mosquée; Span. mezquita, from Arab. masjid, sayada, to adore), the house of prayer in the Mahommedan religion, consisting generally of a large open court (sahn) surrounded by arcades (livan), with a fountain (mida-a) in the centre of the court, for the ablutions necessary before prayer. The principal feature in the mosque is the niche (mihrab), which is sunk in a wall built at right angles to a line drawn from Mecca, and indicates the direction towards which the Moslem should turn when engaged in prayer. The arcades in front of the Mecca niche were sometimes of considerable depth, and constituted the prayer chamber (maksura), portions of which were occasionally enclosed with lattice work. By the side of the niche was the pulpit (minbar), and sometimes in front of the latter a platform (dikka) raised on columns, from which chapters from the Koran were read to the people.

Most mosques have endowed property, which is administered by a warden (nasir), who also appoints the imams and other officials. The larger mosques have two imams; one is called (in Arabia and Egypt) the khatib, and he preaches the sermon on Fridays (the Moslem Sabbath); the other, the ratib, reads the Koran, and recites the five daily prayers, standing close to the mihrab, and leading the congregation, who repeat the prayers with him, and closely follow his gestures. The imams do not form a priestly sect; they generally have other occupations, such as teaching in a school or keeping a shop, and may at any time be dismissed by the warden, in which case they lose the title of imam. Moslem women, as a rule, are expected to say their prayers at home, but in some few mosques they are admitted to one part specially screened off for them.

The earliest mosque erected was that at Mecca, which consisted of a great court, in the centre of which was the Ka‘ba or Holy Stone. The court was surrounded with arcades, all of which constituted the prayer chamber, so that its plan is necessarily different to the normal type; the existing buildings date only from the first half of the 17th century, as the whole mosque was destroyed by a torrent in 1626.

The normal type referred to is best represented in the mosque of 'Amr (see 'AMR-IBN-EL-ASS) at Postat, Cairo; built in A.D. 643 it still retains its original arrangement, though partly rebuilt and increased in its dimensions. The mosque (see fig. 1), now in a somewhat ruined condition, covers an area of about 130,000 sq. ft. with an open court, 240 ft. sq., and a sanctuary or prayer chamber, 160 ft. deep, there being a central avenue and ten aisles on either side. The columns and capitals were all taken from ancient buildings, Egyptian, Roman and Byzantine, and they carry arches of different forms, semicircular, pointed and horseshoe.

The columns and other materials of the mosque of el-Aksa at Jerusalem were taken by Abdalmalk (A.D. 690) from the ruins of Justinian's church of St Mary on Mount Zion, and the central avenue or nave built with them presents the appearance of a Christian church; it however runs north and south, the Mecca niche being at the south end; originally there were seven aisles on each side, now reduced to five. The Kubbet-es-Sakhra, or Dome of the Rock, at Jerusalem, is only a shrine erected over the sacred rock, so that the title often ascribed to it as "the mosque of Omar" is misleading.

The mosque of the Omayyads in Damascus was built by the Caliph Walid in A.D. 705 on the foundations of the basilican church of St John; its plan differs therefore from the normal type in that its arcades run east and west, and the transept in the centre becomes the prayer chamber. The Mecca niche is sunk in the doorway of a Roman temple which formerly occupied the same site, and the substructure of the minaret at the south-west angle is of still more ancient date. The great court on the north side has a lofty cloister round it, so that in many respects it follows the normal type.

The mosque of Ahmad Ibn Tulun, in Cairo (A.D. 879), is the first mosque erected in which the materials were not taken from ancient buildings; it has therefore a special interest as being the earliest genuine example of the Mahommedan style (see ABDARRAHMAN). The walls, piers and arches, are all built in brick, covered with stucco, great portion of which is preserved down to the present day. The plan of the normal type, with a great court in the centre, a prayer chamber four aisles deep on the Mecca side (south-east), and a double aisle on the other three sides. All the arches are pointed and slightly horseshoe, preceding therefore by about two and a half centuries the introduction of the pointed arch into Europe. The piers carrying the arches have shafts at their angles, the earliest examples known, and the decoration of the walls consists of friezes, borders, and impost hands, all enriched with conventional patterns interwoven with cufic characters and modelled in stucco. The windows in the outer walls are filled with pierced stone screens of geometrical design. The architect is said to have been a Coptic Christian who depreciated the destruction of ancient buildings to obtain columns and blocks of stone, and who undertook to design a mosque which should be built entirely in brick, which when coated with stucco and appropriate decorative designs would rival its predecessors.

The next important mosque is that of Kairawan in Tunisia, which was founded by Sidi Othman in A.D. 675, but was partly rebuilt and added to in the following two centuries. Its court covers an area of 38,000 sq. ft., and its prayer chamber is 150 ft. deep, having a central avenue and eight aisles on each side.

The chief interest of the mosque at Kairawan lies in its being the prototype of the great mosque at Cordova, which was built by Abdarrahman in A.D. 780; the earliest portion of the mosque is the prayer chamber (155 ft. wide by 220 ft. deep), which is in front of the entrance gateway to the great court, and consists of a central avenue with five aisles on each side. In A.D. 961 this
portion was extended 150 ft. in the rear by Hakim II., the mihrab and Mecca wall being rebuilt; about 20 years later a further enlargement was made, and eight more aisles were added along the whole eastern side, so that the prayer chamber covered an area of over 148,000 sq. ft. In the 13th century a portion of Hakim’s addition was pulled down to make way for the first cathedral, which was dedicated to the Virgin. The most beautiful portion of the mosque, however, still exists in the prayer chamber of Hakim, where are to be found the earliest examples of the cusped arch and the origin of many of the geometrical patterns in stucco at the Alhambra.

The mosque of el Azhar, “the splendid,” was begun about A.D. 970 by Jauhar, the general of the Fatimite Caliph Moizz, who captured Fostat and founded el Kahira, the present town of Cairo. It was based, therefore, on the great mosque at Kairawan, and although more or less rebuilt, it still preserves its original plan. It has a special interest in being the chief university of the Moslem world, containing some thousands of students (muqawrin), for whom certain parts of the mosque (riwaq) are screened off, according to the country from which they come. Thus special parts are reserved for natives of the various provinces of Egypt, of Morocco, Syria, Arabia, India, Turkey, &c. Each student can, if he is too poor to hire lodgings, live, eat and sleep in the mosque. Each has a large chest in which to keep his clothes and books; these are piled against the walls to a height of seven or eight feet. The students pay no fees, but the richer ones give presents to the lecturers, who sit on the matting in various parts of the sanctuary or cloister, while the students sit round each lecturer in a circle. The usual course of study lasts for three years, though some students remain for much longer. The chief of the lecturers, called the Sheik el-Azhar, receives about £100 a year, the others little or nothing, as regular pay. The Koran, sacred and secular law, logic, poetry, arithmetic, with some medicine and geography, are the chief subjects of study.

Of other mosques in Cairo, the finest is that of Sultan Hasan (fig. 2), completed in A.D. 1360. It differs from the normal type in many respects, as it includes residences for various sects, so that portions of it, with the several stories externally, resemble an immense mansion or warehouse, and this would seem to have led to an important change inside, as instead of a cloister of two or more aisles there are four immense halls all covered with pointed barrel vaults. Beyond the Mecca wall is the tomb of the founder, covered with an immense dome. The entrance doorway on the north-east side is over 80 ft. in height, its summit being decorated with stalactite vaults, one of the grandest features in Mahommedan architecture, only equalled by the magnificent portals of the mosques in India. The central square court, of moderate dimensions, with halls and great recesses, is followed in other examples in Cairo, among which the Tomb of Mogul Khan (c.A.D. 1470) is the most graceful (fig. 3). In this case the central court is roofed over, and has an octagon lantern in the centre; the recesses are covered with horizontal ceilings carried on great beams, the whole being elaborately carved, coloured and gilded; the tomb is covered with the later type of dome, built in stone, and elaborately carved outside with delicate conventional patterns in relief.

Although the conquest of Persia by the Arabs took place in A.D. 641 there are no remnants of mosques there earlier than the 13th century, and the oldest example at Tabriz is evidently, as far as its plan is concerned, a copy of a Byzantine church, departing entirely therefore from the normal plans. The great mosque at Isfahan, built by Shah Abbas the Great (1585–1629), has one great court (225 ft. by 170 ft.) and two smaller ones, all with fountains in them. The prayer chamber is a lofty structure, quite unlike those of Egypt and Kairawan, with a dome 75 ft. in diameter and halls on each side divided into two aisles, each compartment being covered with a dome, in this respect also not following the early normal type, in which domes were on top of tombs.

The mosques of Constantinople are all copies more or less of S. Sophia; they have courts in front with a range of arcades round, and the centre portion forms the prayer chamber, the side aisles serving as passages. The central dome has but a slight elevation outside, but with the numerous cupolas round, and the minarets, it forms a picturesque group which is wanting in the mosques of Kairawan, Cordova, and other examples in North Africa.

In India as in other countries the Mahommedans took possession of the ancient buildings and adapted them to their religious requirements. The materials of the native styles of India, however, did not lend themselves to their utilization as in Syria, Egypt and North Africa, where the columns and capitals formed the substructure of the arcades which surrounded their courts. In the earliest mosque at old Delhi, they adopted the piers and bracketed capitals of the Jaina builders, whom they probably employed to build their mosque. They, however, had no confidence in the arch, which, as the Hindu says, “never sleeps but is always tending to its own destruction,” so that the pointed arch, which had almost become the emblem of the Mahommedan religion, had to be dispensed with for the covered aisles which surrounded the great court, and in the triple entrance gateway the form of an arch only was retained, as it was constructed with horizontal courses of masonry for the haunches, and with long slabs of stone resting one against the other at the top. A similar construction was employed in the great mosque at Ajmere, built A.D. 1200–1211 at the same time as the Delhi mosque. The objection to the arch is more clearly shown

---

1 It is very generally held that this “Blue Mosque” dates only from the 15th century (see TABBIRI).
in the entrance gateway of the Lāl Darwaza or Red Gate mosque at Jaunpur, where an arch (of two rings of ogee shape) is carried by a solid wall, built under it, which is pierced with three doorways with bracket-capitals and architraves, returning therefore to trabeculated construction. The covered aisles of the court of the Jumna Masjid at Jaunpur are in three storeys with piers, bracket-capitals and architraves, bearing therefore no resemblance to the arcades of Kairawan and Cordova, and constituting a different style. There is however one feature which throughout the Mahomedan mosques in India is always found, viz. the dome. But this also in India is built in horizontal courses, so that the form only and not the construction of the Cairene domes is followed. The chief peculiarity of the mosques at Ahmadabad is that, as the style progressed, it became more Indian; in the Jumna Masjid (A.D. 1242) and the Queen’s mosque at Minzapur, the pointed arch exists only in the façades of the prayer chambers; in the mosques built 30 to 40 years later the whole is constructed without a single arch, all the pillars have bracket-capitals, and the domes, which are of very slight elevation, are all built in the trabeculated style. As a contrast to the Ahmadabad mosques, the Kadam Rasul mosque at Gaur in Bengal possesses some characteristics which resemble those of the mosque of Tulun in Cairo, possibly due to the fact that it is entirely built in brick, with massive piers carrying pointed arches.

The climax of Mahomedan work in India is reached in that of the Mogul emperors at Agra, Delhi and Fatehpur-Sikri, in which there is a very close resemblance in design to the mosques of Syria, Egypt, and Persia; the four-centred arch, which is in the Mogul style, finds general acceptance, and was probably derived from Persian sources. The mosque at Fatehpur-Sikri possesses in its great southern gateway, built by Akbar in the second half of the 16th century, the masterpiece of Indo-Saracenic architecture. As a rule, the mosques of India followed the normal plan, with a great central court and aisles round and a prayer chamber in front of the Mecca wall, which in India is always at the west end.

(R. P. S.)

**MOSQUITO** (Span. *mosquito*, a gnat, diminutive of *mosca*, a fly), a term originally applied to many species of small-blood sucking *Diptera* (q.v.), belonging to various families, but now by common consent restricted to those known to naturalists as *Culicidae*, or gnats. Before the year 1890 mosquitoes had never been collected systematically, and had received little notice from entomologists, so that but few genera and comparatively few species were known. Although it had long been suspected that these insects were in some way connected with malaria and other diseases, while the species which now called *Stegomyia calopus* was the carrier of yellow fever had been asserted by Finlay as early as 1881, it was not until the closing years of the 19th century that the brilliant researches of Ross in India, and of Grassi and others in Italy, directed the attention of the whole civilized world to mosquitoes as the exclusive agents in the dissemination of malarial fever. The result has been that in subsequent years mosquitoes have been collected, studied and described by naturalists and medical men in all parts of the globe. Nearly 100 genera and about 700 species of mosquitoes are now recognized, but in all probability the total number of species is not less than 1000.

In general appearance mosquitoes resemble many harmless midges (*Chironomidae*), but may be distinguished by the following characters. (1) The prolongation of the lower lip or labium into a prominent proboscis, which in the female sex contains the full complement of piercing organs found in blood-sucking *Diptera*, namely paired mandibles, paired maxillae, a tubular hypopharynx (the common outlet of the salivary glands), and an upper lip or labrum. (2) The presence of variously formed scales on the body and its appendages: the head is clothed with scales, the thorax with hairs or scales, and the abdomen with either hairs or scales, or both; the legs and veins of the wings are always covered with scales, and the palpi are often (as in some *Anopheles*) conspicuously scaly. (3) The fact that the costal or marginal vein runs completely round the wing. The wings exhibit six longitudinal veins (seven in *Hepiaphlebomyia*), of two which are characteristically forked. The antennae, usually bottle-brush shaped (plumose) in the male sex, are less hairy in the female. The palpi vary in form and in the number of their component segments, and the proboscis, though usually straight, may be curved (as in *Megarhinus*) or otherwise modified in form.

In dividing the *Culicidae* into genera reliance is placed chiefly upon characters derived from the scales on the three divisions of the body and on the wings. A fairly satisfactory attempt at grouping the genera has been made by Lutz (1904), who divides the family into the first place into the *Euoculidae*, with a piercing proboscis (i.e. all ordinary mosquitoes), and the *Culicimorphae* or forms without a piercing proboscis (*Mochlonyx, Corethra*, &c.). It has since been proposed to treat the *Culicimorphae* as a distinct family under the title *Corethridae*, and it is probable that with this modification Lutz’s scheme will meet with general acceptance. The *Euculidae* are divided into the *Anaphelinae* (= *Anopheles*), the larvæ of which have no respiratory siphon, and the *Siphoninae*, or forms in which a respiratory siphon is present in the larval state. The divisions of the *Siphoninae* are the *Ankylorhynchinae* (genera with curved proboscis, e.g. *Megarhinus* and *Toxorhynchites*) and *Orthorhynchinae* (genera with straight proboscis). The latter again are divided into *Metanopinae* (in which the metanotum or posterior region of the thorax is bare) and *Metanotricleae* (in which the metanotum is clothed with bristles or scales). The *Metanopinae* are made up of the *Heteropalpinae* (palpi long in the male, short in the female; sub-families *Culicinae* (*Culex*, *Osornia*, &c.) and *Heptaplebomyinae* (*Cephalophlebomyia*), and *Micropapalinae* [palpi short in both sexes; sub-families *Aedinae* (*Aedes*, &c.) and *Haemagoginae* (*Haemogogus*, *Uromyia*, &c.)]. The *Metanotricleae* are similarly divided on the basis of the palpal characters into two sub-families, *Vulvopalaestinae* or *Hylconopinae* (*Jobytha*, *Rhynochomyia*, &c.) and *Micropalinae* or *Dendromyzinae* (*Wyeomyia*, *Sabethes*, *Limatus*, &c.).

The old genus *Anopheles* (characterized by the palpi being long in both sexes) is now divided into a number of genera according to the character and shape of the scales on the different regions of the body and on the wings. These genera make up the sub-family *Anaphelinae*, and together include over two hundred species. Their genus *Culex*, from which the family takes its name, though it has been similarly split up, is still in its restricted sense larger than any other, and some 200 species are comprised in it alone.

Mosquitoes are found in all parts of the world. Even within the Arctic Circle they are in many localities abundant and excessively bloodthirsty, even in the summer. Under such conditions the deeply-rooted nature of the blood-sucking instinct is most remarkable; for insects whose ancestors for many generations may not have tasted blood will seek for it with the utmost keenness and pertinacity so soon as an opportunity presents itself. Some species are normally phytophagous, and the vast majority, at any rate, appear to be capable of continuing to exist and reproducing their kind upon a purely vegetarian diet. As a rule the blood-sucking habit is confined to the females, but in the case of a few species it is said to be common to both sexes. The thirst for blood is stimulated by heat, and in temperate climates it is only during hot weather that mosquitoes are troublesome. Some species of mosquitoes, such
as the common gnat (Culex pipiens), are rarely found away from human habitations; others seldom or never enter houses, but are met with either in more or less open country, or in the recesses of forests and woods. In Europe and North America the existence of species is ensured by the hibernation of impregnated females, or else the winter is passed in the egg or occasionally in the larval state. In tropical climates with a well-marked dry season mosquitoes pass into a semi-dormant condition during the period when there is little water in which to deposit their eggs. Culicidae are by no means confined to low-lying districts, and have even been met with in the Himalayas at an altitude of 13,000 feet. The wide distribution of certain species is undoubtedly attributable to the agency of ships and trains; under natural conditions mosquitoes seldom travel far from their breeding grounds, although the powers of flight of some species are greater than has been supposed.

The preliminary stages of all mosquitoes are passed in water, either fresh or salt, stagnant or slightly moving. The nature of the breeding-place varies greatly according to the species, and while many of the mosquitoes that infest houses will breed even in the smallest accidental accumulation of water such as may have collected in a discarded bottle or tin, the larvae of other species less closely associated with man are found in natural pools or ditches, at the margins of slow-moving streams, in collections of water in hollow trees and bamboo-stumps, or even in the water-receptacles of certain plants. The eggs are usually deposited on the water itself, and while in the case of certain species, such as Culex pipiens or the widely distributed C. fatigans, they are agglutinated together in masses known as "boats" or "rafts" containing from 50 to 400 ova, those of others, such as the Anophelineae and many Culicinæae (e.g. Stegomyia calopus), are laid separately. The larvae are active and voracious little grub-like creatures (known in the United States as "wrigglers"), with large heads and jaws provided with a pair of brushes, which sweep food-particles into the mouth. Their food consists of minute animal and vegetable organisms, and lie almost horizontally at the surface; they frequently appear as though anchored by the tail to a weed or other object, and possess the curious faculty of completely rotating the head so as to browse on the surface film. Mosquito pupae are comma-shaped (see fig.), and breathe by means of a pair of respiratory trumpets on the thorax.

The majority of mosquitoes are dull in hue, but certain species are brilliantly coloured or conspicuously banded or spotted with white. The Anophelineae have narrow bodies, and generally spotted wings, and when at rest keep body and proboscis in a straight line, often at a considerable angle with the supporting surface; in this way they can be distinguished from Culicinæae, which have a humped-up thorax with which the proboscis forms an angle, and in the resting position keep the body parallel to the support.

The disseminators of malaria are exclusively Anophelineae, but even among these it is only certain species that are dangerous, since the others appear to be incapable of acting as hosts of the parasites. Stegomyia calopus, on the other hand, is a very widely distributed species and the almost certain carrier of yellow fever. The larvae belong to the Culicineae. In the case of filariasis due to Filaria bancrofti, which is common throughout the Tropics, the embryos of the parasite are disseminated by various Culicinæae and Anophelineae (Culex pipiens in Queensland; C. fatigans in the West Indies; Myzomyia rossii in India; Pyrephorus costalis in a large portion of tropical Africa; &c.). Six or seven species of mosquitoes are also the intermediate hosts of Filaria immitis, which infects the right auricle and pulmonary artery of the dog, and occurs throughout the tropics, in southern Europe, the United States of America, and elsewhere.

There is reason to believe that malaria, yellow fever and filariasis are not the only diseases disseminated by mosquitoes. (E. E. A.)

**MOSQUITO COAST AND RESERVE** (Mosquitia or Reserve Mosquita), a division of the republic of Nicaragua, officially styled the department of Zelaya. Pop. (1905), about 15,000. Although its name is sometimes applied to the whole eastern seaboard of Nicaragua—and even to Mosquito in Honduras, i.e. the coast region as far west as the Rio Negro or Tinto—the Mosquito Coast is more accurately defined as a narrow strip of territory, fronting the Caribbean Sea, and extending from about 11° 45' to 14° 10' N. It stretches inland for an average distance of 40 m., and measures about 225 m. from north to south. In the north, its boundary skirts the river Wawa; in the west, it corresponds with the eastern limit of the Nicaraguan highlands; in the south, it is drawn along the river Rama. The chief towns are Bluefields or Blewfield, Magdalena on Pearl Cay, Prinzapolca on the river of that name, Vounta near the mouth of the Cuculua, and Carata near the mouth of the Wawa. Bluefields (pop. about 2000) is the capital and the largest town. It is the seat of a Moravian mission, and has a good harbour, with regular steamship services to Greytown in Nicaragua, and to New Orleans. It exports bananas and other fruit.

The Mosquito Coast is so called from its principal inhabitants, the Mosquito Indians, whose name was corrupted into Mosquito by European settlers and has been entirely superseded by that form except in the native dialects. The Mosquito Indians, of whom there are several tribes, are an unusually intelligent people, short of stature and very dark-skinned. Their colour is said to be due to intermarriage with shipwrecked slaves.

The first white settlement in the Mosquito country was made in 1630, when the agents of an English chartered company—of which the earl of Warwick was chairman and John Pym treasurer—occupied two small cays, and established friendly relations with the Indians. From 1645 to 1850 Great Britain claimed a protectorate over the Mosquito Indians; but little success attended the various endeavours to plant colonies, and the protectorate was disputed by Spain, the Central American republics, and the United States. The opposition of the United States was due very largely to the fear that Great Britain would acquire a privileged position in regard to the proposed interoceanic canal. In 1848, the seizure of Greytown (San Juan del Norte)
by the Mosquito Indians, with British support, aroused great excitement in the United States, and even involved the risk of war. But by the Clayton-Bulwer Treaty of 1850 both powers pledged themselves not to fortify, colonize or exercise dominion over any part of Central America; and in November 1859 Great Britain delegated its protectorate to Honduras. This caused great dissatisfaction among the Indians, who shortly afterwards revolted; and on the 28th of January 1860 Great Britain and Nicaragua concluded the treaty of Managua, which transferred to Nicaragua the suzerainty over the entire Caribbean coast from Cape Gracias à Dios to Greytown, but granted autonomy to the Indians in the more limited Mosquito Reserve (the area described above). The local chief accepted this change on condition that he should retain his local authority, and receive a yearly subvention of £1000 until 1870. But on his death in 1864 Nicaragua refused to recognize his successor. The reserve nevertheless continued to be governed by an elected chief, aided by an administrative council, which met in Bluefields; and the Indians denied that the suzerainty of Nicaragua connoted any right of interference with their internal affairs. The question was referred for arbitration to the emperor of Austria, whose award published in 1880, upheld the contention of the Indians, and affirmed that the suzerainty of Nicaragua was limited by their right of self-government. After enjoying almost complete autonomy for fourteen years, the Indian prohibited the presence of foreigners on the 20th of November 1874 their territory was formally incorporated in that of the republic of Nicaragua, as the department of Zelaya.

MOSS, a seaport of Norway, in Smaalenene amt (county), on the east shore of Christiania Fjord, 37 m. S. of Christiania by the Gothenburg railway. Pop. (1900), 8041. Here was signed, on the 14th of August 1814, the convention which united Norway to Sweden. Timber and wood pulp are chief exports, grain and coal are imported. The port affords 13 to 22 ft. of water beside the quays.

MOSSAMEDES, a town of Portuguese West Africa, capital of the district of Mossamedes, on the south side of Little Fish Bay (Bay of Mossamedes or Anga do Negro). Pop. about 3000. The harbour affords excellent sailing. The position of Lagos is lost from the harbour and crosses the semi-desert coast region to the fertile Chella plateau. Mossamedes is the headquarters of an important fishing industry (see La Géographie, March 1908).

MOSEL BAY, the name of a bay, town and division of the Cape province, South Africa. The bay lies midway between Table Bay (Cape Town) and Port Elizabeth roadstead. Like most of the South African bays it does not afford good anchorage. Westward, however, it is sheltered by Cape St. Blaise, on which is a lighthouse. The town lies on the west side of the bay, Cape St. Blaise stretching beyond to the S.E. Mossel Bay is 250 m. by sea and 312 m. by rail E. by S. of Cape Town. Pop. (1904), 4500. The port ranks fourth in importance among the seaports of the Cape and does a large forwarding trade. Vessels load and discharge by means of lighters. Mossel Bay is a station on the direct Cape Town–Port Elizabeth railway. The Mossel Bay division of the province has an area of 707 sq. m., and a population (1904) of 10,700, of whom 40% were whites.

MOSSLEY, a market town and municipal borough in the West Lancashire parliamentary division, Lancashire, England, 105 m. E.N.E. of Liverpool, by the London & North Western railway. Pop. (1901), 13,432. It lies in the valley of the Tame, close to the junction of the boundaries of Lancashire, Cheshire and Yorkshire, and is surrounded by sharplyrising high ground, especially eastward. The Huddersfield canal passes it. Across the river from the town ancient earthworks (Burton Castle), of British origin, are seen, and a Roman road passing them, and running north and south is also traceable. Mossley has foundries, mill-work, woollen factories, and large cotton-spinning mills. It was incorporated in 1885, and the corporation consists of a mayor, 6 aldermen, and 16 councillors. Area, 3622 acres.

MOSSOP, HENRY (1729–1774), Irish actor, was born in Dublin, and made his first stage appearance there, at the Smock Alley Theatre, as Zanga in Young’s tragedy, The Revenge, in 1749. His first London appearance was made in 1751 under Garrick’s management, as Richard III. He returned to Ireland in 1759, and, playing with Barry, added to his laurels, but when he attempted management on his own account, he ruined Barry and went bankrupt himself, dying in poverty on the 27th of December 1774.

MOST, JOHN [JOSEPH] (1846–1906), German-American anarchist, was born in Augsburg, Bavaria, on the 3rd of February 1846. He was apprenticed to a bookbinder, worked at this trade in Germany, Austria, Italy and Switzerland in 1863–1868, and then became a writer of Socialist pamphlets and paragraphs, and editor of Socialist sheets in Chemnitz and Vienna, both suppressed by the authorities, and of the Freie Presse in Berlin, being repeatedly arrested for his violent and cynical attacks on patriotism and conventional religion and ethics, and for his gospel of terrorism, preached in prose and in many songs such as Der Freiheitsstreiter—Liederkranz (5th ed., 1873). Some of his experiences in gaol were recounted in Die Bastille am Plattensee: Blätter aus meinem Gefängnis,-Tagebuch (1876). In 1874–1878 he was a member of the German Reichstag, but he failed to be re-elected, was expelled by the Socialist organization, went to France but was forced to leave in 1879, and then settled in London. There he founded the “red” organ—it was printed in red—Die Freiheit, in which he expressed his delight in June 1881 over the assassination of Alexander II. of Russia and for this was imprisoned for a year and a half. He then resumed the publication of Die Freiheit in New York. He was imprisoned in 1886, again in 1887, and in 1902, the last time for two months for publishing after the assassination of President McKinley an editorial in which he argued that it was no crime to kill a ruler. He died in Cincinnati on the 17th of April 1906. See his Memoiren (New York, 1903).

MOSTAGANEM, chief town of an arrondissement in the department of Oran, Algeria, 44 m. E.N.E. of Oran, on a plateau 278 ft. high, half a mile from the Mediterranean coast. The town is separated into European and native quarters by a deep ravine, the Ain Sefra, through which passes a considerable stream. The native quarter, called Tijit, occupies the eastern slopes of the ravine and the level ground above, and is dominated by the kubbas of two marabouts. A railway line, completed in 1859, 122 m. long, connects Mostaganem with Tiaret, the most convenient place for visiting the Jedars monuments. (See Algeria.)

Mostagam occupies the site of a Roman town. The ancient harbour was destroyed by earthquake in the reign of the emperor Gallien. The present port is entirely artificial. The existing town appears to date from the time of the Almoravides, who built the citadel, now turned into a prison. It passed into the possession of the rulers of Tlemçen and was captured by Arouj Barbarossa in 1516, and became part of his brother Khaïr-ed-Din’s kingdom. In the 16th century the town enjoyed a period of great commercial prosperity, and its population rose to 40,000. The re-awakening of the town dates from the French occupation in 1833. Pop. (1906) of the town, 19,328, of the commune 22,017, of the arrondissement, comprising 27 communes, 333,684.

In the vicinity of Mostaganem are the Dahra mountains, honeycombed with caves. In 1845, in one of these caves, a French force, commanded by Colonel Péllissier, afterwards commander-in-chief of the French army in the Crimea, destroyed over 800 Arabs—men, women and children—by suffocation, by filling the mouths of the cave with faggots and then setting them on fire.

MOSTAR, the capital of Herzegovina, situated 81 m. S.W. of Sarajevo, on the river Narenta, and on the railway from Sarajevo
MOSUL—MOTANABBI

The language of the people of Mosul is a dialect of Arabic, partly influenced by Kurdish and Syriac. The Moslems call themselves either Arabs or Kurds, but the prevalent type, very different from the pure Arabian Bagdad, proves the Aramean origin of many of their number. Of the Christians the community of the Chaldeans, i.e., those who have gone over from Nestorianism to Catholicism, seems to be the most important; there are also Syrian Catholics and Jacobites. Mosul has for several centuries been a centre of Catholic missionary activity, the Dominicans especially, by the foundation of schools and printing-offices, having made a marked impression upon an intelligent and teachable population. There are very few Protestants. The town is the seat of British, French and Russian consulates.

Mosul shares the severe alternations of temperature experienced by upper Mesopotamia. The summer heat is extreme, and in winter frost is not unknown. Nevertheless the climate is considered healthy and agreeable; copious rains fall in general in winter. The drinking water is got from the muddy Tigris. At the north-east corner of the town is a sulphur spring, and 4 leagues to the south there is a hot sulphur spring (Hamman 'All), much frequented by invalids.

Mosul probably occupies the site of a southern suburb of ancient Nineveh (q.v.) but it is doubtful whether the older name of Mesopotamia has been preserved in the modern Al-Ma'asili (Arabic: "the place of connexion"); it is, however, certain that a town with the Arabic name Al-Ma'asili stood here at the time of the Moslem conquest (636 A.D.). The town reached its greatest prosperity towards the beginning of the decline of the caliphate, when it was for a time an independent capital. The dynasty of the Hamdanids reigned in Mosul from 934, but the town was conquered by the Syrian Oukidhs in 990. In the 11th century it belonged to the Seljukis, and in the 12th, under the sway of the Atabegs, particularly of Zenki, it had a short period of splendour. Saladin besieged it unsuccessfully in 1182. The Persians occupied Mosul for a short time in 1192, until it was, soon afterwards, recovered by sultan Murad IV. The government of the pashalik was long hereditary in the originally Christian family of the 'Abd-al-Jallil, until the Porte, during the course of the 19th century, succeeded after a long and severe contest in establishing a more centralized system of government.

The vilayet of Mosul lies mainly east of the Tigris. It is divided into three sanjaks, Mosul, Shehrozir and Suleimanil, and has an area of 20,000 sq. m. Pop. 255,000 (Moslems 245,000, Christians 30,000 and Jews 500).

See Karl Ritter, "Asien," vol. vii, in Die Erdkunde (Berlin, 1844). A map of the town accompanies J. Cernik's paper, "Studienexpedition durch die Gebiete des Euphrat und Tigris," in Ergänzungsheft No. 45 of Petermanns Mitteilungen (Gotha, 1876); Parry, Six Months in a Syrian Monastery (1895); E. Sachau, Am Euphrat und Tigris (Berlin, 1890); Baron von Oppenheim, Vom Mittelmeer zum Persischen Golf (Berlin, 1890).

MOSZKOWSKI, MORITZ (1854–), Polish musical composer, was born at Breslau, and studied at Dresden and Berlin. He started as a pianist, and had a great success at the chief European centres. He was made a member of the Berlin Academy in 1889. In 1897 he settled in Paris. He became a prolific composer both for piano and orchestra, but is best known by his Spanish dances, written for four hands on the piano, and his Waltzes. His opera Boabdil was performed at Berlin in 1892.

MOTALA, a town of Sweden, in the district (län) of Östergötland, on the east side of Lake Vetter at the outflow of the river Motala, 175 m. S.W. by W. of Stockholm by rail. Pop. (1900), 3047. It is on the Göta canal route (q.v.). The town was founded in 1880, but the Motala mechanical works, 2 m. east, were founded in 1833 by the Göta Canal Company under the direction of Daniel Fraser, an Englishman. Iron war-ships, railway locomotives, iron bridges, machinery, &c., are built; the company has branches in Norrköping, Gothenburg, and elsewhere.

MOTANABBI, strictly Al-Mutanabbi (Abū-T-Tayyib Ahmad ibn al-Lusain of Kufa) (915/6-956), the most famous representative of Arabian poetry. He was born in Baghdad, the son of a slave, named al-Thabit, and is said to have learned to read and write before he was six years old. He was initiated into the secrets of the science of poetry by a certain Khatib, under whose protection he began to write. His writings were collected after his death by his friend, Abu 'Abd Allah Muhammad ibn Marwan, and are now preserved in the manuscript library of the Omayyad mosque at Damascus. They consist of love poems, elegies, and imitations of the poets of Persia and India. "His language is pure and chaste, his style fluent and graceful. His poetry is a perfect model of elegiac and impassioned verse." (Erdkunde.)
tative of the last period of Arabic poetry, was the son of a water-carrier, and is said to have picked up much of the literary knowledge for which he was afterwards famous by haunting the book-stalls of his native city. He spent too, some years of his youth among the nomads of the Syro-Arabian desert, learning their purer dialect, and becoming imbued with their self-reliant spirit. Thus he grew up a brave proud man, a gallant warrior as well as a poet, not easily satisfied either with wealth or honours, indifferent to the Koran and to the facts and prayers of Islam, but untainted by the looseness of morals common to the poets of those days. At first he essayed a perilous road to distinction, appearing in the character of a prophet in the desert between the Euphrates and Syria, where he formed a considerable party, but was arrested by the governor of Emesa (Homs). A prison cooled his enthusiasm. The name of al-Mutanabbi clung to him, however, and is that by which he is still commonly known. Regaining his liberty, he had to struggle for a time with poverty and neglect. But his poetical talents at length found him patrons, and in 948 he became attached to the court of the famous warrior and patron of letters, Saif ad-daulâl, prince of Aleppo, to whom many of the best fruits of his muse were dedicated, and by whose side he approved his valor in the field. But he had rivals who knew how to inspire jealousy between him and the prince, and an angry scene with the grammarian Khālilavâlî, in which the latter closed a philological dispute by striking Mutanabbi, in the very presence of the prince and without rebuke from him, led the poet to leave the court and seek a new career in the realm of the Ikshîds (957). He now took as his patron and the object of his eulogies Kâfur, the regent of Egypt—a black eunuch who knew how to open the poet's lips by great gifts and honours. Mutanabbi, however, sought a higher reward, the government of Sidon, and at length broke with Kâfur, wrote satires against him, and had to fly for his life to Kufah (961). In the next great panegyric of Shirâz, and on a journey from Shirâz to Xufa he was waylaid and slain by a chieftain of the Asad, whose kinsfolk he had satirized (September 965).

The poetry of Mutanabbi is to European taste much less attractive than the verses of the ancient Arab poets, being essentially artificial and generally unreal, though it has great technical merits and displays lively fancy and considerable inventive power. Oriental taste places him on a very high pedestal, as may be judged from the fact that more than forty commentaries were written on his works (cf. D. S. Miller, A Grammar of the Persian, 3rd ed., 1906). Dietrich's edition of the poet (Berlin, 1858–1861), gives the commentary of Wâhîdi (d. 1075); the Egyptian edition of 1870 has the commentary of 'Ukbârî (d. 1230). A convenient edition is that published with a commentary by Nâsîr ul-Yâzîdî at Beirut (1882). See R. A. Nicholson, A Literary History of the Arabs (London, 1907), pp. 304–313.

**MOTET, a musical art-form of paramount importance in the 16th century. The word is of doubtful etymology, and probably its various uses and forms in the 13th and 14th centuries connect with more than one origin. Thus motus suggests motul or melody; and probably represents the notion underlying the use of the term motet us or motells to designate one of the middle parts in a vocal combination. On the other hand the obvious connexion between the Italian word motetto (diminutive of motto) with the French mot (in the sense of bon mot) is in conformity with the use of a protoe art-form contemporary with the conductus and rondel of these early epochs of music.**

The only really definite and mature art-form denoted by the word motet is that of the 16th-century pieces of ecclesiastical music in one or two (rarely more) continuous movements, for the most part on Biblical or other ecclesiastical prose texts. The word is, however, used for any single Latin-text composition in continuous form, not set sequentially and not forming a permanent part of the mass. Thus Palestrina's Stabat mater is included among his motets; though the text is metrical and rhymed, and the style, though continuous, is far from being that of the typical polyphonic motet. The title of motet is also occasionally loosely used for ecclesiastical works, such as many of the numbers in the *Magnus opus musicum* of Orlando di Lasso and the dedicatory motet at the beginning of Palestrina's fifth book. And in this way it is sometimes applied to compositions not to Latin text; as in Josquin's *Déploration du Jehan Obenheim*, where all except the *canto fermo* is in French.

The most important kind of motet is that which is intimately connected with the solemn mass for a particular holy day. Such motets are sung between the *Credo* and the *Sanctus* of the mass. They are, in typical cases, founded on the Gregorian tones of their texts, and the mass is founded on the same themes, thus giving the whole service a musical unity which has never since been approached in any church music even under Bach. When a motet was not founded on Gregorian tones it was still possible for the composer to design a mass on the same themes, and most of the titles of 16th-century masses, when they do not indicate a secular origin, indicate either the motet or the Gregorian tones on which they are founded. Thus Palestrina's masses *Assumpta est Maria*; *O admirabile commercium*; *Dum complurenter*; *Hodie Christus natus est*; *Dies sanctificatus*; *Veni sponsa Christi*, and the second *Missa Tu es Petrus* are magnificent examples selected almost at random from the masses which the composer has founded on his own motets of the same name. When such masses are performed, whether in a concert-room or church, it is indisputable that the motet ought always to be included. Sometimes one composer founded a mass on another composer's motet; thus Soriano's fine *Missa, Nos autem gloriari*, is based upon a motet by Palestrina. When a motet was in two movements the second movement almost always ended with the last clauses of the first, both in text and in music, thereby sometimes producing a distinctly modern impression of da capo form.

In later times the term motet is little more than a name for any choral composition of clearly single design; and the fact that such compositions have often been sung, like the 16th-century motet, between the *Credo* and *Sanctus* of High Mass, has nothing to do with their character as an art-form. Bach's motets are great German choral works in several movements, with no written accompaniment, though there is internal and external evidence that they were accompanied from score by the organ. Handel's motets belong to his Italian period and are simply Latin cantatas of various kinds, with instrumental accompaniment. The later meanings attached to the word are quite indefinite, and have no common idea, except that the motet is nowadays the shortest kind of sacred choral music.

(D. F. T.)

**MOTH,** in entomology, any lepidopterous insect belonging to the division Heterocera, as distinguished from the Rhopalocera, or butterflies; formerly confined to the small nocturnal insect (belonging to the genus *Tinea*), which breeds in fur, clothes, &c. (see LEPIDOPTERA). The word in O.Eng. is *meiphy,* and corresponds to Ger. *Motte.*

**MOTHER,** the term for the female parent of a child. The word, like father, is common to Indo-European languages, cf. in Teutonic languages, Ger. *Mutter, Du. moeder,* Swed. and Dan. *moder,* Gothic is the exception in Teutonic languages, the word being *ôiti,* *ôita,* father; from Lat. *mater* come, in Romanic, Fr. *mère,* It., Sp. and Port., *madre.* Greek has *mère,* (Attic and Ionic), *mère* (Doric). The Russian word is *mat.* The Sansk. *mata* points to an original derivation from a stem *ma,* to measure, or make. Of the many transferred applications of "mother" may be mentioned those to the church, to nature, to the earth, and to a city or nation, as the parent of other cities, nations, colonies, &c. As a title "mother" is particularly applied to the head of a religious community of women. For "mother of pearl" see PEARLS. There is a particular application of "mother" to the scum which rises to the surface of a liquor during the process of fermentation, and also to a mass of gummy stringy consistency formed in vinegar in the process of acetic fermentation, hence known as "mother of vinegar" (see VINEGAR). This is usually, however, taken to be another word altogether, and connected with Du. *modder,* mud, mire.
MOTHERWELL, W.—MOTION, LAWS OF

MOTHERWELL, WILLIAM (1797–1835). Scottish poet, anti-
quary and journalist, was born at Glasgow on the 12th of October
1797, the son of an ironmonger. At the age of fifteen he was
apprenticed in the office of the sheriff-clerk at Paisley, and
employed as an office of the sheriff-clerk at Paisley in 1810. He spent his leisure in
the collecting materials for a volume of local ballads which he
published in 1810 under the title of The Harp of Renfrewshire.
In 1827 he published a further instalment in Minstrelsy Ancient
and Modern, prefaced by an excellent historical introduction.
He contributed verses to newspapers and magazines, Jeanie
Morrison, My Heid is like to rend, Willie, and W e b's Could Well
being his best-known poems. He became editor of the Paisley
Advertiser in 1828, and of the Glasgow Courant in 1830.
A small volume of his poems was published in 1832, and a larger volume
with a memoir in 1846, reissued, with additions, in 1848.

MOTHERWELL, a municipal and police burgh of Lanarkshire,
Scotland. Pop. (1851), 900; (1901), 34,418. It is situated near
the right bank of the Clyde, 13 m. S.E. of Glasgow by the
Caledonian railway. It takes its name from an old well dedi-
cated to the Virgin, and owes its rapid increase to the coal
and iron mines in the neighbourhood. It has large iron and
steel works, bridge-building being a distinctive trade. Boats,
steamers, and ironmongers' wares are also made, and there
are brick, tile and fire clay works. The public buildings include
the town-hall, theatre and hospital; the park was presented in
commemoration of Queen Victoria's Jubilee.

MOTION (Lat. motio, from movere, to move), in English law, an
application made to a court during the progress of an action,
and either before or after judgment has been pronounced. The
object of a motion is to invoke the assistance of the court in
matters that are of a pressing character, and require to be
speedily dealt with. A motion differs from a petition in that it is
made viva voce in open court and is founded on a written state-
ment. Motions are either motions of course or special motions.
A motion of course is made ex parte without notice, and is
not mentioned in court, the party being entitled as of right.
Motions of course are confined to the chancery division of the High Court.
A special motion is made in open court, and must be supported by
proper evidence. Special motions are made either ex parte or on
notice. On all ex parte applications the utmost good faith must be
observed. Ex parte motions in the King's bench division, are
usually made to a divisional court. A motion for judgment is
a proceeding whereby a party to an action moves for judgment
of the court in his favour. See Rules of the Supreme Court,
Ovs. xi., lii.

MOTION, LAWS OF. Before the time of Galileo (1564–1642)
hardly any attention had been paid to a scientific study of the
motions of terrestrial bodies. With regard to celestial bodies,
however, the case was different. The regularity of their
diurnal revolutions could not escape notice, and a good deal
was known 2000 years ago about the motions of the sun
and moon and planets among the stars. For the statement
of the motions of these bodies uniform motion in a circle
was employed as a fundamental type, combinations of motions
of this type being constructed to fit the observations. This
procedure—which was first employed by the great Greek
astronomer Hipparchus (2nd century B.C.), and developed by
Ptolemy three centuries later—did not afford any law con-
necting the motions of different bodies. Copernicus (1473–
1543) employed the same system, and greatly simplified the
application of it, especially by regarding the earth as rotating
and the sun as the centre of the solar system. Kepler (1571–
1630) was led by his study of the planetary motions to reject this
method of statement as inadequate, and it is in fact incapable
of giving a complete representation of the motions in question.
In 1609 and 1610 Kepler published his new laws of planetary motion,
which were subsequently shown by Newton to agree with the
results obtained by experiment for the motion of terrestrial bodies.
The earliest recorded systematic experiments as to the motion
of falling bodies were made by Galileo at Pisa in the latter years
of the 16th century. Bodies of different substances were
employed, and slight differences in their behaviour accounted
for by the resistance of the air. The result obtained was
that any body allowed to fall from rest would, in a
vacuum, move relatively to the earth with constant
acceleration; that is to say, would move in a straight line,
in such a manner that its velocity would increase by equal
amounts in any two equal times. This result is very nearly
correct, the deviations being so small as to be almost beyond the
reach of direct measurement. It has since been discovered,
however, that the magnitude of the acceleration in question is
not exactly the same at different places on the earth, the range
of variation amounting to about 1/2 %. Galileo proceeded to
measure the motion of a body on a smooth, fixed, inclined plane,
and found that the law of constant acceleration along the line
of slope of the plane still held, the acceleration decreasing in
magnitude as the angle of inclination was reduced; and he inferred
that a body, moving on a smooth horizontal plane, would move
uniformly in a straight line if the resistance of the air,
and friction due to contact with the plane, could be elimi-
nated. He went on to deal with the case of projectiles, and was
led to the conclusion that the motion in this case could be re-
garded as the result of superposing a horizontal motion with
uniform velocity and a vertical motion with constant acceler-
ation, the latter identical with that of a merely falling body;
the inference being that the path of a projectile would be a
parabola except for deviations attributed to contact with the air,
and that in a vacuum this path would be accurately followed.
The method of superposition of two motions may be illustrated
by such examples as that of a body dropped from the mast of a
ship moving at uniform speed. In this case it is found that
the body falls relatively to the ship as if the latter were at rest,
and alights at the foot of the mast, having consequently pursued
a parabolic path relatively to the earth.

The importance of these results, limited though their scope
was, can hardly be overrated. They had practically the effect
of suggesting an entirely new view of the subject, namely, that
a body uninfluenced by other matter might be expected to move,
relatively to some base or other, with uniform velocity in a
straight line; and that, when it does not move in this way, its
acceleration is the feature of its motion which the surrounding
conditions determine. The acceleration of a falling body is
naturally attributed to the presence of the earth; and, though the
body approaches the earth in the course of its fall, it is easily
recognized that the conditions under which it moves are only
very slightly affected by this approach. Moreover, Galileo
recognized, to some extent at any rate, the principle of simple
superposition of velocities and accelerations due to different sets
of circumstances, when these are combined (see MECHANICS).
The results thus obtained apply to the motion of a small body,
the rotation of which is disregarded. When this case has been
sufficiently studied, the motion of any system can be dealt with
by regarding it as built up of small portions. Such portions,
small enough for the position and motion of each to be sufficiently
specified by those of a point, are called "particles."

Descartes helped to generalize and establish the notion of the
fundamental character of uniform motion in a straight line, but
otherwise his speculations did not point in the direc-
tion of sound progress in dynamics; and the next important
advance in this respect was due to Huygens (1629–1695). He attained
correct views as to the character of centrifugal force in connexion
with Galileo's theory; and, when the fact of the variation
of gravity (Galileo's acceleration) in different latitudes first became
known from the results of pendulum experiments, he at once
perceived the possibility of connecting such a variation with the
fact of the earth's diurnal rotation relatively to the stars. He
made experiments, simultaneously with Wallis and Wren, on the
collision of hard spherical bodies, and his statement of the results
(1666) included a clear enunciation of the conservation of linear
momentum, as demonstrated for these cases of collision, and
apparently correct in certain other cases, mass being estimated by
weight. But Huygens's most important contribution to the

N8359
subject was his investigation, published in 1673, of the motion of a rigid pendulum of any form. This is the earliest example of a theoretical investigation of the rotation of rigid bodies. It involved the adoption of a point of view as to the relation between the motions of bodies of different forms, which practically amounted to a perception of the principle of energy as applied to the case in question.

We owe to Newton (1642-1727) the consolidation of the views which were current in his time into one coherent and universal system, sometimes called the Galileo-Newton theory, but commonly known as the "laws of motion"; and the demonstration of the fact that the motions of the celestial bodies could be included in this theory by means of the law of universal gravitation. A full account of his results was first published in the Principia in 1687.

Such statements as that a body moves in a straight line, and that it has a certain velocity, have no meaning unless the base, relative to which the motion is to be reckoned, is defined. Accordingly, in the extension of Galileo's results for the purpose of a universal theory, the establishment of a suitable base of reference is the first step to be taken. Newton assumed the possibility of choosing a base such that, relatively to it, the motion of any particle would have only such divergence from uniform velocity in a straight line as could be expressed by laws of acceleration dependent on its relation to other bodies. He used the term "absolute motion" for motion relative to such a base. Many writers on the subject distinguish such a base as "fixed." The name "Newtonian base" will be used in this article. Assuming such a base to exist, Newton admitted at the outset the difficulty of identifying it, but pointed out that the key to the situation might be found in the identification of forces; that is to say, in the mutual character of laws of acceleration as applied to any given body and any other by whose presence its motion is influenced. In this connexion he took an important step by distinguishing clearly the concept of "mass" as a universal property of bodies distinct from weight.

There can be no doubt that the development of correct views as to mass was closely connected with the results of experiments with regard to the collision of hard bodies. Suppose two small smooth spherical bodies which can be regarded as particles to be brought into collision, so that the velocity of each, relative to any base which is unaffected by the collision, is suddenly changed. The additions of velocity which the two bodies receive respectively, relative to such a base, are in opposite directions, and if the bodies are alike their magnitudes are equal. If the bodies though of the same substance are of different sizes, the magnitudes of the additions of velocity are found to be inversely proportional to the volumes of the bodies. But if the bodies are of different substances, say one of iron and the other of gold, the ratio of these magnitudes is found to depend upon something else besides bulk. A given volume of gold is found to count for this purpose about two and a half times as much as the same volume of iron. This is expressed by saying that the density of gold is about two and a half times that of iron. In fact, experiments upon the changes of velocity of bodies, due to a mutual influence between them, bring to light a property of bodies which may be specified by a quantity proportional to their volumes in the case of bodies which are perceived by other tests to be of one homogeneous substance, but otherwise involving also another factor.

The product of the volume and density of a body measures what is called its "mass." The mass of a body is often loosely defined as the measure of the quantity of matter in it. This definition correctly indicates that the mass of any portion of matter is equal to the sum of the masses of its parts, and that the masses of bodies alike in other respects are equal, but gives no test for comparison of the masses of bodies of different substances; this test is supplied only by a comparison of their motions in opposite directions, and the ratio of their magnitudes determines the ratio of the masses of the particles; the motion being reckoned relative to any base which is unaffected by the change. It is found that this gives a consistent result; that is to say, if by an experiment with two particles A and B we get the ratio of their masses, and by an experiment with B and a third particle C we get the ratio of the masses of B and C, and thus the ratio of the masses of A and C, we should get the same ratio by a direct experiment with A and C. For the numerical measure of mass that of some standard body is chosen as a unit, and the masses of other bodies are obtained by comparison with this. Masses of terrestrial bodies are generally compared by weighing; this is found by experiment to give a correct result, but it is applicable only in the neighbourhood of the earth. Familiar cases can readily be found of the perception of the mass of bodies, independently of their tendency to fall towards the earth. The mass of any portion of matter is found to be permanent under chemical and other changes, and this fact adds to its importance as a physical quantity. The study of the structure of atoms has suggested a connexion of mass with electrical phenomena which implies its dependence on motion; but this is not inconsistent with the observed fact of its practical constancy, to a high degree of accuracy, for bodies composed of atoms.

The Galileo-Newton theory of motion is that, relative to a suitably chosen base, and with suitable assignments of mass, all accelerations of particles are made up of mutual (so-called) actions between pairs of particles, whereby the two particles forming a pair have accelerations in opposite directions in the line joining them, of magnitudes inversely proportional to their masses. The total acceleration of any particle is that obtained by the superposition of the component accelerations derived from its association with the other particles of the system severally in accordance with this law. The mutual action between two particles is specified by means of a directed quantity to which the term "force" is appropriated. A force is said to act upon each of two particles forming a pair, its magnitude being the product of the component acceleration of the particle of which it acts, and its direction that of this component acceleration. Thus each mutual action is associated with a pair of equal forces in opposite directions. Instead of the operation of superposing accelerations, we may compound the several forces acting on a particle by the parallelogram law (see Mechanics) into what may be called the resultant force, the total acceleration of the particle being the same as if this alone acted. The theory depends for its verification and application upon the fact that forces can be identified and classified. They can be recognized by Application of the theory to their reciprocal character, and it is found to be possible to connect them by permanent laws with the recognizable physical characteristics of the systems in which they occur. A generalization of Galileo's results takes the form that under constant conditions of this kind, force (defined in terms of motion) is constant, and that the superposition of two sets of conditions, if their independence can be secured, results in superposition of the forces involved. Particular laws of force may be suggested by a study of the simplest cases in which they are manifested, and from them results may be obtained by calculation as to the motions of systems of any given structure. Such results may be tested by direct observation.

It should be noted that, within a limited range of application to terrestrial mechanics, the most convenient way of attacking the question of the relations of forces to the physical conditions of their occurrence may be by balancing their several effects in producing motion; thus avoiding in the first instance both the choice of a base and the consideration of mass. This procedure is useful as a preliminary step in the study of the subject. It does not, however, afford a convenient starting-point for a general theory, because it is apt to involve some confusion of phenomena which, from the point of view of the Galileo-Newton theory, are distinct in character.

Newton's law of gravitation affords the most notable example of the process of verification of a law of force, and incidentally of the Galileo-Newton theory. As a law of acceleration of the planets relatively to the sun, its approximate agreement with
Kepler's third law of planetary motion follows readily from a consideration of the character of the acceleration of a point moving uniformly in a circle. Newton tells us that this agreement led him to adopt the law of the inverse square of the distance about the year 1665–1666, before Huygens's results as to circular motion had been published. At the same time he thought of the possibility of terrestrial gravity extending to the moon, and made a calculation with regard to it. Some years later he succeeded in showing that Kepler's elliptic orbit for planetary motion agreed with the assumed law of attraction; he also completed the co-ordination with terrestrial gravity by his investigation of the attractions of homogeneous spherical bodies. Finally, he made substantial progress with more exact calculations of the motions of the solar system, especially for the case of the moon. The work of translating the law of gravitation into the form of astronomical tables, and the comparison of these with observations, has been in progress ever since. The discovery of Neptune (1846), due to the influence of this planet on the motion of Uranus, may be mentioned as its most dramatic achievement. The verification is sufficiently exact to establish the law of gravitation, as providing a statement of the motions of the bodies composing the solar system which is correct to a high degree of accuracy. In the meantime some confirmation of the law has been obtained from terrestrial experiments, and observations of double stars tend to indicate for it a wider if not universal range. It should be noticed that the verification was begun without any data as to the masses of the celestial bodies, these being selected and adjusted to fit the observations.

The case of electro-magnetic forces between two conductors carrying electric currents affords an example of a statement of motion in terms of force of a highly artificial kind. It can only be contrived by means of complicated mathematical analysis. In this connexion a statement in terms of force is apt to be displaced by more direct and more comprehensive methods, and the attention of physicists is directed to the intervention of the ether. The study of such cases suggests that the statement in terms of force of the relations between the motions of bodies may be only a provisional one, which, though it may summarize the effect of the actual connexions between them sufficiently for some practical purposes, is not to be regarded as representing them completely. There are indications of this having been Newton's own view.

The Newtonian base deserves some further consideration. It is defined by the property that relative to it all accelerations of particles correspond to forces. This test involves only changes of velocity, and so does not distinguish between two bases, each of which moves relatively to the other with uniform velocity without rotation. The establishment of a truly Newtonian base presupposes knowledge of the motions of all bodies. But practically we are always dealing with limited systems, so any actual determination must always be regarded as to some extent provisional. In the treatment of the relative motions of a limited system, we may use a confessedly provisional base, though it may be necessary to introduce corrections, or at least approximate to, take account of the existence of bodies outside the system, or of the rotation of the base employed relative to a more correct one. Such corrections may be made by the device of applying additional unpaired, or what we may call external, forces to particles of the system. These are needed only so far as they introduce differences of accelerations of the several particles. The earth, which is commonly employed as a base for terrestrial motions, is not a very close approximation to being a Newtonian base. Differences of acceleration due to the attractions of the sun and moon are not important for terrestrial systems on a small scale, and can usually be ignored, but their effect (in combination with the rotation of the earth) is very apparent in the case of the ocean tides. A more considerable defect is due to the earth having a diurnal rotation relative to a Newtonian base, and this is never wholly ignored. Take a base attached to the centre of the earth, but without this diurnal rotation. A small body hanging by a string, at rest relatively to the earth, moves relatively to this base uniformly in a circle; that is to say, with constant acceleration directed towards the earth's axis. What is done is to divide the resultant force due to gravitation into two components, one of which corresponds to this acceleration, while the other one is what is called the "weight" of the body. Weight is in fact not purely a combination of forces, in the sense in which that term is defined in connexion with the laws of motion, but corresponds to the Galileo acceleration with which the body would begin to move relatively to the earth if the string were cut. Another way of stating the same thing is to say that we introduce, as a correction for the earth's rotation, a force called "centrifugal force," which combined with gravitation gives the weight of the body. It is not, however, a true force in the sense of corresponding to any mutual relation between two portions of matter. The effect of centrifugal force at the equator is to make the weight of a body there about 0.35% less than the value it would have if due to gravitation alone. This represents about two-thirds of the total variation of Galileo's acceleration between the equator and the poles, the balance being due to the ellipticity of the figure of the earth. In the case of a body moving relatively to the earth, the introduction of centrifugal force only partially corrects the effect of the earth's rotation. Newton called attention to the fact that a falling body moves in a curve, diverging slightly from the plumb-line vertical. The divergence in a fall of 100 ft. in the latitude of Greenwich is about 0.1 in. Foucault's pendulum is another example of motion relative to the earth which exhibits the fact that the earth is not a Newtonian base.

For the study of the relative motions of the solar system, a provisional base established for that system by itself, bodies outside it being disregarded, is a very good one. No correction for any defect in it has been found necessary; moreover, no rotation of the base relative to the directions of the stars without proper motion has been detected. This is not inconsistent with the law of gravitation, for such estimates as have been made of planetary perturbations due to stars give results which are insignificant in comparison with quantities at present measurable.

For the measurement of motion it must be presumed that we have a method of measuring time. The question of the standard to be employed for the scientific measurement of time accordingly demands attention. A definition of the measurement dependent on dynamical theory has been a characteristic of the subject as presented by some writers, and may possibly be justifiable; but it is neither necessary nor in accordance with the historical development of science. Galileo measured time for the purpose of his experiments by the flow of water through a small hole under approximately constant conditions, which was of course a very old method. He had, however, some years before, when he was a medical student, noticed the apparent regularity of successive swings of a pendulum, and devised an instrument for measuring, by means of a pendulum, such short periods of time as sufficed for testing the pulse of a patient. The use of the pendulum clock in its present form appears to date from the construction of such a clock by G. B. van den Earthen in 1667; it is first mentioned as a timekeeping device in the second edition of the Principia, distinguishing what he called "absolute time" from such measures of time as would be afforded by any particular examples of motion; but he did not give any clear definition. The selection of a standard may be regarded as a matter of arbitrary choice; that is to say, it would be possible to use any continuous time-measurer, and to adapt all scientific results to it. It is of the utmost importance, however, to make, if possible, such a choice of a standard as shall render it unnecessary to date all results which have any relation to time. Such a choice is practically made. It can be put into the form of a definition by saying that two periods of time are equal in which two physical operations, of whatever character, take place, which are identical in all respects except as regards lapse of time. The validity of this definition depends on the assumption that operations of different kinds all agree in giving the same measure of time, such allowances as experience dictates being made for changing conditions. This assumption has successfully stood all
tests to which it has been subjected. All clocks are constructed on the basis of this method of measurement; that is to say, on the plan of counting the revolutions of a wheel, W. W. R. Ball, sole owner, of a device capable of continual repetition with a certain degree of accuracy, and possibly also of automatic compensation for changing conditions. Practically clocks are regulated by reference to the diurnal rotation of the earth relatively to the stars, which affords a measurement on the repetition principle agreeing with other methods, but more accurate than that given by any existing clock. We have, however, good reasons for regarding it as not absolutely perfect, and there are some astronomical data the tendency of which is to confirm this view.

The most important extension of the principles of the subject since Newton's time is to be found in the development of the theory of energy, the chief value of which lies in the fact that it has supplied a measurable link connecting the motions of systems, the structure of which can be directly observed, with physical and chemical phenomena having to do with motions which cannot be similarly traced in detail. The importance of a study of the changes of the \( \frac{d\psi}{dt} \) depending on squares of velocities, or what is now called the "kinetic energy" of a system, was recognized and published by W. W. R. Ball and it has been perceived (at any rate for special cases) that an increase in this quantity in the course of any motion of the system was otherwise explainable by what we now call the "work" done by the forces. The mathematical treatment of the subject from this point of view by Lagrange (1736-1813) and others has afforded the most important forms of statement of the theory of the motion of a system that are available for practical use. But it is to the physicists of the 19th century, and especially to Joule, whose experimental results were published in 1843-1849, that we practically owe the most notable advance that has been made in the development of the subject—namely, the establishment of the principle of the conservation of energy (see Energy and Energy). The energy of a system is the measure of its capacity for doing work, on the assumption of suitable connections with other systems. When the motion of a body is checked by a spring, its kinetic energy being destroyed, the spring, if perfectly elastic, is capable of restoring the motion; but if it is checked by friction no such restoration can be immediately effected. It has, however, been shown by W. W. R. Ball, if properly managed, a capacity for doing work by virtue of its configuration, so in the case of the friction there is a physical effect produced—namely, the raising of the temperature of the bodies in contact, which is the mark of a capacity for doing the same amount of work. Electrical and chemical effects afford similar examples. Here we get the link with physics and chemistry alluded to above, which is obtained by the recognition of new forms of energy, interchangeable with what may be called mechanical energy, or that associated with sensible motions and changes of configuration.

Such general statements of the theory of motion as that of Lagrange, while releasing us from the rather narrow and strained view of the subject presented by detailed analysis of motion in terms of force, have also suggested a search for other forms which a statement of elementary principles might equally take as the foundation of a logical scheme. In this connexion the interesting scheme formulated by W. W. R. Hertz (1854) deserves notice. It is important as an addition to the logic of the subject rather than on account of any practical advantages which it affords for purposes of calculation.

**MOTIVE**

(MOTIVE) (from Lat. *motere*, to move), in psychology, a general term signifying any element of consciousness which prompts an agent to a decision. The older psychology usually regarded motives as strictly analogous to mechanical forces exerting pressure or tension, and explained human action as necessarily determined by the resultant of various, possibly conflicting, motives. Contemporary psychological research tends to show with increasing clearness that we must recognize a power of decision in the self, and that the analogy of mechanical forces is inadequate to explain the facts. On this view motives will be regarded as solicitations to act in a certain direction, while the self decides by throwing its volitional weight on the side of the motive which it regards as preferable. The solicitations may come from the most diverse sources: they may be mere desires to avoid some pain or to gratify some appetite; or they may be of higher origin, such as the motive of patriotism, or the desire to advance knowledge. Purposes or ends are often termed motives. "Conflict of motives" means sometimes a conflict of purposes, when the agent has adopted two different lines of action and has decided, either by its own means of solicitation, or by some other way, to give up one or other. It is better to call purposes or ends by those names when they have been definitely adopted by the agent: while they are still under deliberation the term "motive" may be used.

**MOTLEY, JOHN LOUTHROP** (1814-1877), American historian, son of Thomas Motley, was born on the 15th of April 1814 at Dorchester (now a part of Boston), Massachusetts, and graduated at Harvard in 1831. He then studied at Göttingen and Berlin, becoming a friend of Bismarck at Göttingen, and after a period of European travel returned in 1834 to America, where he continued his legal studies. In 1837 he married Mary Benjamin (d. 1874), a sister of Park Benjamin, and in 1839 he published anonymously a novel entitled *Morton's Hope*, or *The Memoirs of a Provincial*. In 1841 he entered the diplomatic service as secretary of legation in Russia, but resigned his post within three months. Returning to America, he soon entered definitely upon a literary career. Besides contributing various historical and critical essays to the *North American Review*, including a remarkable essay on the *Politics of the Puritans*, he published in 1849, again anonymously, a second novel, entitled *Morton's Mistake*. The project of writing a history of Holland had begun to take shape in his mind, and he had already done a large amount of work on this subject when, finding the materials at his disposal in the United States inadequate, he went to Europe in 1851. The next five years were spent at Dresden, Brussels and the Hague in investigation of the archives, which resulted in 1856 in the publication of *The Rise of the Dutch Republic*, which became very popular. It speedily passed through many editions, was translated into French, and also into Dutch, German and Russian. In 1860 Motley published the first two volumes of its continuation, *The United Netherlands*. This work was on a larger scale, and embodied the results of a still greater amount of original research. It was brought down to the truce of 1669 by two additional volumes, published in 1867. In 1861, just after the Civil War had broken out in America, Motley wrote two letters to the *Times* defending the Federal position, and these letters, afterwards reprinted as a pamphlet entitled *Causes of the Civil War in America*, made a favourable impression on President Lincoln, who asked him to stay. He was appointed United States minister to Austria in 1864, a position which he filled with great success until his resignation in 1867. Two years later he was sent to represent his country in London, but in November 1870 he was recalled by President Grant. After a short visit to Holland, he again took up his residence in England, where the *Life and Death of John Barrow* appeared in two volumes in 1874. Ill health now began to interfere with his literary work, and he died at Frampton Court, near Dorchester, Dorset, on the 29th of May 1877, leaving three daughters. The merits of Motley as an historian are undeniable great. He has...
MOTLEY—MOTORS, ELECTRIC

told the story of a stirring period in the history of the world with full attention to the character of the actors and strict fidelity to the vivid details of the action. But it may safely be said that his tale is best where most unvarnished, and probably no writer of the same rank has owed less to the mere sparkle of highly polished literary style.

An excellent edition of his historical works was published in nine volumes in London in 1903-1904. See the Correspondence of John Lathrop Motley, edited by G. W. Curtis (New York, 1886); O. W. Holmes, John Lathrop Motley, a Memoir (Boston, 1878); M. D. Conway, Biographical Introduction to The Rise of the Dutch Republic (London, 1896); and John Lathrop Motley and his Family: Further Letters and Records (1910), edited by his daughter, Mrs Susan St John Mildmay.

MOTLEY, i.e. of many colours, a term particularly used of the parti-colored dress of the professional "fool" (q.v.) of the middle and later ages. The origin of the word is probably to be found in "mote" (O. Eng. mot), a particle of dust, &c., hence a spot or patch. "Mottle," a blotch or spot, is probably a back formation of motley.

MOTMOT. According to Hernandez in his Historia avium Novae Hispaniae (p. 52), published at Rome in 1651, this is the Mexican name of a bird which he described well enough to leave no doubt as to what he meant; but the word being soon after printed Motmot by Nieremberg and others gave rise to the Latinized form Motmot, invented by M. J. Brisson as a generic term, which has since been generally adopted by ornithologists, though motmot has been retained as the English form. Linnaeus knew of only one species of motmot, and referred it to his genus Ramphastos (properly Rhamphastus) under the name of R. momota. This is the Momotus brasiliensis of modern ornithologists, and from its geographical range cannot be the original Motmot of Hernandez, but is most likely the "Guira guainumbi" of Marcgrave.

The motmots form the sub-family Momotinae, which with the Todineae (see Toddy) form the family Momotidae of Coraciiform birds, the nearest allies being rollers (q.v.) and kingfishers (q.v.). In outward appearance the motmots have an undoubted resemblance to bee-eaters, but, though beautiful birds, various shades of blue and green predominating in their plumage, they do not exhibit such decided and brilliant colours; and, while the bee-eaters are only found in the Old World, the motmots are a purely Neotropical form, extending from southern Mexico to Paraguay, and the majority of species inhabiting Central America and the West Indies. They are about the size of the small birds in the family Motacillidae, which are generally of a dull tawny or topaz colour, and insects caught on the wing. The nest of one species, as observed by Robert Owen, is at the end of a hole bored in the bank of a watercourse, and the eggs are pure white and glossy (Ibis, 1861, p. 65). Little else has been recorded of their ways.

The Momotidae form but a small group, containing about six genera, of which the best known are: Momotus, Baryphthengus, Hylomanes, Eumomota, Aspatha and Priornorhynchus, and the number of species is very small. While all have a general resemblance in the serrated edges of the bill and many other characters, Momotus has the most distinctive character, being a broad beak, with an old hooked end, and the tip of the bill is covered with a peculiar hook. The wings are short, and the tail is composed of twelve rectrices. The plumage is usually dark brown, and the body is covered with a glossy plumage, which is usually greenish in color. The eggs are white, and the nest is usually placed in a hole in the ground or in a hollow log. The diet consists of insects, small birds, and occasionally small mammals. (A. N.)

MOTORS, ELECTRIC. Fundamentally, electric motors are electric generators reversed in function: they convert into mechanical energy the continued stresses between two electromagnetic fields relatively movable, just as generators convert into electromagnetic stresses the mechanical energy applied to them. Since no transformation of energy is ever absolutely quantitative, the conversion just considered are not accomplished without loss of energy to about the same extent in both cases. The sources of this loss are ohmic loss in the conductors, hysteresis, friction of bearings and brushes, air friction and eddy currents; the sum of these losses in large modern machines does not exceed 5 or 6%. The torque of the motor is the dynamical result of the electromagnetic stresses between the magnetic field of the motor and that due to the armature currents, the latter field being proportional to the strength of the current sheet due to the numerical strength of the current and the number of its effective convolutions. This applies to all types of motors, if one remembers that whenever either of these two stress factors is a periodic variable, as in the case of alternating motors, the torque is proportional to their geometrical co-directed product and not merely to their numerical product. At this point it will be convenient to distinguish between the various types of motors. The first broad distinction is between continuous-current and alternating-current motors, a distinction rather of convenience than of necessity, for in point of fact the two depend upon the same fundamental principles and can be considered on precisely the same lines.

Electric motors may be conveniently divided as follows:

(A) Continuous Current.

1. Separately excited.
2. Series-wound constant current.
5. Shunt-wound constant potential.

(B) Alternating Current.

1. Synchronous constant potential.
2. Induction-polyphase constant potential.
3. Induction-monophase constant potential.
4. Repulsion-commutating.
5. Series-commutating.

Of these, the series-wound constant potential, shunt-wound constant potential, and polyphase induction motors do a very large proportion of the active work of power transmission: the first mentioned furnish power for electric railways; the second chiefly for distribution; the third is widely used in the generation of electric power, while the third are mainly relied upon in long-distance transmission systems. The fourth and fifth groups of class (B) are old in principle but have been slow in practical development. They include many modifications and transition forms not involving radical changes in the principles or properties of the machines. Their chief use has been for electrical traction, with reference to which they have, in the main, been developed, and their performance is best at low frequency, 15 to 25 cycles per second.

In class (A) in general, for a certain value of the torque current must be forced through the armature against the motor electromagnetic force which results from the rotation of the armature in a given field. This demands a certain greater applied electromagnetic force to produce the current required, which is determined by the effective electromagnetic force, equal to the geometrical difference between the applied and motor electromagnetic forces, and by the impedance of the armature. For steady currents this last is of course the same as the ohmic resistance, just as for steady electromagnetic force the geometrical and the numerical difference of the applied and motor electromagnetic forces are coincident. The torque depends, as heretofore noted, on the field strength and the strength of the current sheet due to the current thus determined. For small values of the torque the speed practically depends upon the applied electromagnetic force and the field, so that if the former and the latter be constant the speed is also sensibly constant. This is likewise the case if the armature resistance be very small; and in general the variations of speed at constant potential are determined by the product of this resistance and the torque, while the absolute speed depends essentially upon the field strength. Motors for low speed or high
electromotive force must have both a strong field and many turns upon the armature, so that both the fundamental stresses may be large. As the field is generally strong—to secure economy of iron—low-voltage and high-voltage machines differ principally in the number of armature turns. For variable speed, this latter factor being fixed, field strength and applied electromotive force are the factors easily altered, and most of the speed variation is accomplished by changing one or both of them. Torque, neglecting field distortion, is at a maximum when the current is the greatest possible at the given applied voltage—that is, when the motor is at rest. With a small armature resistance this current is generally far too great for convenience; hence the motors are usually started with a rheostat in series with the winding if the current is not limited by the generator itself. The torque then depends on the sum of the resistances in circuit, and can be made just sufficient to start the motor under the required load. By the same device the motor can run at reduced speed, although with a considerable loss of energy in the current, that is, as a rule, difficult to get effective speed variation in motors of any kind without serious loss of energy. The field can be changed within wide limits only by a considerable increase of the iron in the magnetic circuit, the applied electromotive force cannot usually be varied except by increasing the resistances in circuit, and the number of armature turns cannot be varied without complication, although the effective number can be modified by shifting the brushes, probably at the expense of sparking. Altogether, if the speed variation demanded be more than 15 or 20%, it causes, in one way or another, considerable expense and trouble, particularly if each speed must be closely held irrespective of load. No large change in absolute speed can readily be made without considerable change in the percentage variation of speeds at various loads. Practically, the best results are obtained from motors of very low armature resistance, in which the field or the applied electromotive force, or both, are varied. The whole problem is nearly identical with the production of constant potential or constant current from generators driven at constant speed, and is solved by similar means. For any one absolute speed a generator can be made to give constant potential, nearly irrespective of load, by compound winding. Similarly, a motor may give a very nearly constant speed at constant potential by a differential winding in series with the armature, weakening the field as the armature current rises. This device, however, obviously increases the energy required for magnetization, and decreases the effective torque at starting. Practically, the best continuous-current motors can be made to hold their speed to within 1 or 2% from no load to full load. Commercial machines, however, generally vary from 5 to 10% in speed. With respect to the direction or rotation of a motor, the torque changes sign with a change of sign in either field or armature current, but not with a change of sign in both. The input of the motor is numerically equal to the product of the current and the applied electromotive force, while the output is determined by the product of the current and motor electromotive force; hence the efficiency of the motor as a transformer of energy is the ratio between these two quantities. The output is a maximum when the applied electromotive force is double the motor electromotive force, and the efficiency is a maximum when the motor and applied electromotive forces are substantially equal. At the point of maximum output the speed is that sufficient to reduce the current to one-half its static value. No motor is worked at or near this point, except momentarily, on account of the low efficiency and severe heating in the armature. These theoretical values are slightly modified in practical machines by the small miscellaneous losses subject to independent variations. The use of the iron depends in considerable part on the degree of normal design by the temperature they can safely endure. As a rule the working temperature, which is commonly reached only after six hours or more of continuous running, should not rise more than 40° to 50° F. above the temperature of the surrounding air. In case of traction motors and others subjected to occasional severe overloads, separated by periods of rest or of subnormal load, the temporary rise of temperature tolerated may be much higher, say 60° to 75° F., after a run of an hour or so. The temperature of the air is assumed at 70° F. in most cases, and the temperature of the motor-windings is preferably ascertained by the rise in electrical resistance due to the heating. Thermometers can seldom be so applied as to measure the full heating effect.

The actual output obtainable from a motor structure of given dimensions under these conditions with respect to heating depends chiefly upon the practicable rotative speed of the armature, since the chief losses are proportional to the torque, while the mechanical output at given torque is approximately proportional to the speed. Most makers utilize a single structure for several standard motors varying in speed and output, a 15 h.p. machine at, say, 1200 r.p.m. becoming a 10 h.p. at 800 r.p.m. or a 20 h.p. at 1600 r.p.m. There is no practically fixed relation between the rating and the speed, although it is approximately linear, for in winding the same carcass for different speeds the calculations settle rather by commercial convenience than by exact determinations. Motors generally have approximately the same efficiencies as the corresponding sizes of generators. Small motors, say from 1 to 5 h.p., are commonly of 70–80% efficiency at full load, medium sized machines of 5 to 50 h.p. about 80 to 90%, and the larger sizes run up to 95% or thereabouts. In the effort to get low-speed motors without immoderately increasing the cost they are generally dropped a little in efficiency and allowed to run hotter than if wound for higher speeds.

The weight of motors per h.p. of output is therefore very variable. In machines of medium size and speed it is likely to be 30 to 75 lb per h.p., falling to 30 or 40 in large or specially high speed machines, and rising to 80 or 100 lb in small or very low speed motors. High-voltage motors, particularly if small, lose somewhat in relative output on account of the space taken up by the necessary insulation.

In all ordinary motors the magnetization of the iron is, for economy of material, pushed high; and hence the field, even at heavy loads, is fairly stable and the conditions of commutation remain good. When, however, motors are designed to stand severe overloads, or to admit of a wide range of speed regulation by varying the field strength, the commutation is likely to be unstable, and severe sparking may result. To meet this condition the commutating-pole motor—really a recrudescence of an old idea—has been introduced on a considerable scale. In this construction auxiliary pole pieces, excited by series coils from the motor circuit, are set midway between the ordinary field poles. The office of these poles is to neutralize the magneto-motive force due to the armature winding, thus checking field distortion, and also to ensure the proper reversal of the current in the armature coil directly under the brush. Of the total magneto-motive force due to the windings of the commutating pole, the major part, perhaps three-fourths, is devoted to the former work and the remainder to the latter, the proportion varying widely according to the design of the motor. The result of this construction is excellent, sparkless commutation being ensured over a wide range of load and field strength. The commutating-pole motor is intrinsically more expensive and slightly less efficient than the ordinary type, but for the particular kind of service it is designed to perform is extremely effective. It gives promise of especial value in high-voltage traction motors.

(A) 1. Separately excited Motors are interesting principally on account of the very efficient method of speed regulation possible by their use. In this method the field of the motor is excited from the supply mains, and the armature current is furnished by a motor-generator running at constant speed. A rheostat in the shunt field winding enables the applied electromotive force to be varied to any desired extent, and hence the working motor can be given full torque at any speed up to that assigned by the maximum value of the electromotive force which can be applied to the armature. Moreover, if the armature resistance be small, the motor is fairly self-regulating at all speeds. The effect is rather startling, since the motor may be given a very great torque when it is merely turning over at a few revolutions per minute; and although the process is complicated, it leads to excellent results, and is widely used where delicate speed regulation is required.
MOTORS, ELECTRIC

(A) 2. Series-wound Constant-current Motors were early worked to a considerable extent on arc-lights circuits, but have now passed out of use save in a small number of constant-current power-transmission systems on the continent of Europe. In these motors the magnetic circuit is designed so as to keep the armature reaction in phase with the torque being constant. They will not start with more than a certain definite load, but once started the speed will increase until the added load (internal or external) balances the torque. The type is intrinsically the most efficient, but must be supplied with particular methods as are adopted to secure constant current in arm machines.

The most successful device in most cases is to vary the field strength by shunting the field coils or to vary the number of effective armature turns. Some of the constant-current electromotors now in use are fixed and cannot be varied without mechanical rather than by purely electrical means—in the first case by an automatic rheostat, and in the second by an automatic brush shifter, but neither is wholly satisfactory. Nevertheless, such motors have proved capable of excellent commercial service in many applications.

(A) 3. Series-wound Constant-potential Motors comprise nearly all the motors used for electric traction—aggregating not less, probably, than one and a half million horse-power; hence they are of great practical importance. But their disadvantages are such that for any specialized machines with very powerful armatures and fields strongly saturated at all working values of the current, the brushes have an invariable position. Such motors behave much like separately-excited ones, except that a certain regulation must be obtained by varying the applied electromotive force. In early traction motors this variation depended upon inserting a rheostat; in modern practice it is customary to employ two, or even three fields, for example, one set of which are in series with the armature while the other is in parallel, one point of which is in series with a shunt, and the other point is in parallel with the armature. The variation is obtained by means of the electromotive force at the series field and the current of the shunt field. The speed of these motors is controlled by varying the armature and field circuits, and it is entirely independent of the speed of the prime mover.

(A) 4. Series-wound Motors with Interpolated Current and Potential are capable of combining the advantages of the shunt and series motor. The armature and field windings of a shunt motor and a field shunt motor, forming a dynamical unit. This system is occasionally used with good results in power transmission. Assuming the motor field to be saturated; if the speed is to be constant the applied electromotive force must be decreased, and the field must also be decreased to maintain the same ratio of armature to field current. If the regulator has a field less fully saturated, the increase in current demanded by the increment of torque in the motor can be made not only to raise the applied electromotive force enough to compensate for the armature resistance, but for the total resistances in circuit, including the line. With this difference in saturation the motor will automatically maintain constant speed. The fields of the machines need not be designed for a given saturation, since shunting them with a suitable resistance will give the same result.

(A) 5. Shunt-wound Motors at Constant Potential are the mainstay of continuous-current distributions for industrial purposes. At constant potential the field remains sensibly constant and the torque is direct. The motor may be considered much like a separately-excited motor, and the armature resistance being generally very small, the speed is very nearly constant, varying less than 1% from no load to full load in the best commercial machines. Even a comparatively low constant of this type of motor can be regulated to regulate with great precision, as in the previous case. If the motor field be only moderately saturated, its strength, and hence the direct electromotive force, rises only on the instantaneous value of the current, and the motor will work at constant speed, either at constant load or constant speed, in spite of small variations of voltage. If speed variation be required, it can be obtained to a moderate extent by a rheostat in the field. At starting, or when the motor is at a standstill, it may be necessary to modulate the armature field to start the motor forward or reverse. The condition of complete reversibility is that the instantaneous values of the currents, and the instantaneous values of the angular displacements between poles and armature coils, shall be exactly equal. This evidently requires that the rotation of the motor should be symmetrical. For this purpose for the sake of symmetrical disposition of the poles and the armature, the field and the armature circuits should be symmetrical. Here, as before, the torque depends on the two fundamental stresses, but the torque has no definite sign in the absence of an initial rotation. The instantaneous value of the torque depends on the instantaneous value of the armature current and displacement. The speed of the motor being variable, its direct electromotive force depends only on the effective excitation, including the armature reactions, and it may or may not, according to the conditions of load, be in phase with the impressed electromotive force. In the case of the continuous-current motor, the motor output is numerically equal to the product of current and motor electromotive force. In the case of the direct-current motor, the output is numerically the product of the torque in the motor, the speed, and the effective current. These quantities are usually not in phase, in alternating motors the activity is determined by the co-directed part of their product. The current in the alternating motor depends, not on the ohmic resistance of the armature, but on the difference between the applied current and the effective resistance of the motor; the phase angle depends on the change in the phase of the current and the load torque. The phase angle is determined by the difference between the applied current and the effective resistance of the motor; the phase angle depends on the change in the phase of the current and the load torque. The phase angle is determined by the difference between the applied current and the effective resistance of the motor; the phase angle depends on the change in the phase of the current and the load torque. The phase angle is determined by the difference between the applied current and the effective resistance of the motor; the phase angle depends on the change in the phase of the current and the load torque.

Synchronous motors sometimes cause serious trouble by "pumping," a phenomenon closely allied to the surging of current between alternators in parallel, and due to similar causes. If not due to the presence of eddy currents, or to the difference between the electromagnetic forces in the field and the armature, the motor is treated exactly like an alternator, to be thrown in parallel with the supply circuit. A synchronous motor will pull itself up to speed by its own momentum, if brought up to its synchronous speed, but this is a very large moment of force. Over and above this moment of its own, it can be brought to speed by giving it a small initial rotation and raising the generator speed and exciting the armature with current. When the machines are in synchronism, the current can be shut down without any change of load or phase, producing fluctuations in the electromagnetic force. In the system great enough to interfere seriously with incandescent lighting, and continuing with nearly uniform amplitude and frequency for hours or days, the phenomenon is with the conditions, but in the same machine the frequency is nearly constant. The fluctuation affects both the armature and the field circuits, the former inductively by changes in the armature magnetomotive force, and the latter inductively by changes in the field current. The effect of changing the frequency of the exciting current until a neutral point is reached, and then, is to change the phase angle in the motor, the pole faces serving as secondary conductors, but requiring no large currents in that starting themselves that it is better practice to bring to a point of synchronizing impulses. According to the fact that the direct current voltage is dependent on the alternating current voltage of supply, the converter cannot advantageously be used to control
the power factor by variation of the field strength, but the field can be adjusted once for all to hold the power factor reasonably near unity, provided independent means are available for so adjusting the applied alternating voltage as to give the required result at the commence of the current. It is obvious that the regulation of the converter is not necessarily sufficient to carry the new load. If the secondary member is of very low resistance, the slip behind synchronous speed varies very small, and even at full load—less than 2% in motors developed for this particular property, motors for running at synchronous speed. For this reason, the slip is large from synchronous speed; and if resistance be added to the secondary member by interpolating rheostats in its circuits, the motor can be made to produce uniform torque over a wide range of speed, with constant current through the armature. The percentage slip is the percentage of energy lost in the secondary member, as likewise in continuous-current motors if one regards their slip as that of the motor electromagnetic force would be reduced, and the pole-pair current would be increased in the former. The motor is therefore properly designed, with a very powerful torque, even up to three or four times the full load running torque of the same motor. With a very low-secondary resistance member this torque demands an enormous armature and high field current, and the shunt circuited transformer, and the lag in the secondary circuit is considerable. In motors in which this large starting torque is objectionable, it may be reduced very greatly by interpolating resistances to the armature of a continuous-current motor, and by controlling the windings of the two being in series and approximately equivalent. In this case the normal motor-electromotive force is reached at approximately half synchronous speed, and half the energy is developed in the pole-pair, the rest by the frequency changer, which requires a lag of the secondary to be added at starting and cut out afterwards, particularly in cases where large torque is necessary. If great starting torque is not necessary, the primary electromagnetic force is often diminished by inductive reactance added to the armature of the transformer from which the motor is fed. Both methods of starting are in commercial use on a very large scale.

In efficiency and closeness of speed regulation and good general results, the polyphase induction motors approximate very closely to the best form of direct-current motors. However, a certain amount of lag between primary electromagnetic force and current, which causes the apparent input to be larger than the mechanical output, as generally happens in alternating-current work. The ratio of maximum lag to primary current is a measure of the power-factor of the motor. In well-designed modern machines this is usually from 85 to 90%, at rated load; it should seldom fall below the former figure, and rarely rises more than 1 or 2% above the latter, though in units of the armature, which has to be taken in account. Condensers have sometimes been employed in combination with such motors to increase the power-factor, and with considerable success, particularly in maintaining the power-factor during starting and cut out afterwards, particularly in cases where large torque is necessary. In order to increase the power-factor by making the structure more efficient, considered merely as a transformer. The clearances in ordinary use are seldom greater than 15 in., even in motors as large as 1000 horse power, and the machines acting entirely as polyphase motors, and sometimes by auxiliary phase-windings supplied by derived current from the main circuit, or merely short-circuited on themselves and receiving induced currents from the main winding. Both these auxiliary windings are wound in the same winding, and in the case of a so-called elliptical rotary field, i.e. one produced by the composition of two unequal magnetizations, in this case at some indeterminate angle, seldom large. Once up to speed, the single-phase motors act much like the polyphase. They are conspicuously weak in the matter of power-factor, however, as well as in that of starting-torque, and have by as yet not come into very extensive commercial use, although under special conditions they have been and are successfully employed. A theoretically interesting form of induction.
MOTOR VEHICLES

The term "motor-car" is one which was primarily employed in America to denote the car or carriage containing the electro-motor used for propelling an electric tramcar or train of carriages on rails, but of late years it has been more frequently applied in Great Britain to light automobile or mechanically-propelled vehicles.

(A) 1. Induction Motors.—The term "induction" is derived from the fundamental frequency of acting on the armature of the motor, so that the condition for steady torque is always fulfilled, its amount depending on the position of the brushes. Were these either in line with, or exactly at right angles to, the field poles, the torque would be zero—in the first case from lack of angular displacement, and in the second from lack of secondary current. The brushes being skewed, however, the secondary current is maintained at a suitable value, and the motor runs in a definite direction. The general principle is that of a transformer with a movable secondary winding, and the conductors of the secondary winding can be made to start if need be, by a second circuit of current through the brushes of opposite sign, which are short-circuited on each other and placed at an angle with the field magnetization. By this device the magnetic axis of the armature is held at a fixed angle with the magnetic axis of the field, so that the armature never fulls, its amount depending on the position of the brushes.

The advantage of this change is that the commutator is eliminated, save at starting, and the motor becomes practically a constant speed machine like any other properly-designed simple induction motor. Partially-speed induction motors can be made to start if need be, by a second circuit of current through the brushes of opposite sign, which are short-circuited on each other and placed at an angle with the field magnetization. By this device the magnetic axis of the armature is held at a fixed angle with the magnetic axis of the field, so that the armature never fulls, its amount depending on the position of the brushes.

The pure repulsion-commutating motor, worked as such, on the other hand, resembles a series-wound motor in its characteristics, having no fixed speed and being capable of running far above normal speed, or even in reverse, provided a result is maintained by the brushes between the armature and field magnetizations, whereby the torque conditions are preserved. Above the nominal synchronous speed, however, difficulties of commutation set in, but magnetic thrusts of this type which is the current, for wide ranges of speed. The power factors of these motors compare well, both in starting and in running, with those of the best pure induction motors, and their efficiencies are similar. These machines are used for light dynamos as well as for Alternating current motors.

Instead of simply skewing the brush line in the repulsion motor, an entirely analogous effect may be produced by dividing the field coils into sections or by making them in pairs and connecting them in series, so as to divide the field into two pairs of opposite fields, separated at a definite angle from each other, and so arranged that they are capable of being brought into juxtaposition at any instant. The effect of this is to divide the virtual reactance of the armature as the speed rises, practically nullifying it at synchronous speed. In alternating current motors the usual method of controlling the field is to connect or disconnect the conductors of the armature commutator to the field coils. In this way the field conductors are brought into juxtaposition and the armature reaction is neutralized. In some motors of this type the commutator is introduced by auxiliary winding in series and in quadrature with the main field, instead of by supplementary brushes. The use of auxiliary winding is not confined to this class of motor, and they are rather numerous, and out of them have come some excellent single-phase motors now widely used for traction purposes.

(B) 4. Repulsion-commutating Motors constitute a class of single-phase motors which has risen to considerable commercial importance. They are fundamentally induction motors in the sense that the armature currents are supplied by the inductive action of the field. The armature winding is, however, partially opposite in sign to that of the field, and the brushes are similarly opposite in sign, which are short-circuited on each other and placed at an angle with the line of field magnetization. By this device the magnetic axis of the armature is held at a fixed angle with the magnetic axis of the field, so that the armature never fulls, its amount depending on the position of the brushes. Were these either in line with, or exactly at right angles to, the field poles, the torque would be zero—in the first case from lack of angular displacement, and in the second from lack of secondary current. The brushes being skewed, however, the secondary current is maintained at a suitable value, and the motor runs in a definite direction. The general principle is that of a transformer with a movable secondary winding, and the conductors of the secondary winding can be made to start if need be, by a second circuit of current through the brushes of opposite sign, which are short-circuited on each other and placed at an angle with the field magnetization. By this device the magnetic axis of the armature is held at a fixed angle with the magnetic axis of the field, so that the armature never fulls, its amount depending on the position of the brushes.
MOTOR VEHICLES

This direction until 1824, from which date a number of these vehicles were constructed and used with considerable success, taking the form of stage coaches propelled by steam, and weighing some 3 or 4 tons unloaded. Some of these ran regular passenger services, notably between Cheltenham and Gloucester, attaining average speeds of 10 to 14 m. per hour; but great oppostion was met with owing to the narrow prejudice of those whose interests related to horse-haulage, and every obstruction was offered in the shape of prohibitive tolls and legislative enactments. The result was that steam carriages were driven off the roads in favour of railways, although the select committee of the House of Commons appointed in 1831 to inquire into the subject reported completely in favour of their adoption (as did also that of 1873). In 1861 the first Locomotives on Highways Act was passed, but the crushing blow came in 1865, when the legislature prescribed (1) that the number of persons required to drive the locomotive should be increased to three; (2) that a man should precede with a red flag; (3) that the maximum limit of speed should be reduced to 4 m. per hour; and (4) that they should be forbidden ever to blow off steam, &c. These restrictions were confirmed rather than relieved by the 1878 act. Although these acts were created to deal with heavy traction, the famous 1881 appeal in the court of queen's bench placed every type of self-propelled vehicle, from a traction engine down to Bateman's steam tricycle, under their narrow limitations. This resulted in the development of the heavy traction engine, and light motor vehicles were little more heard of in Great Britain. There were a few exceptions, however, notably the steam vehicles of Rickett (1866), Carrett (1864), Tangye (1862), Yarrow (1862), Holt (1866), Todd (1870), Perkins (1870), Mackenzie (1875) and Blackburn (1878), and some electrical carriages made by Elwell (1881), Ward (1886) and Volk (1888). An important departure was that of Butler, who constructed in 1885 what is believed to be the first vehicle (a tricycle) propelled by an internal combustion engine in England (fig. 2); he used the vapour of benzoline exploded electrically. Later, Roots successfully employed heavy oil, as did Knight. The chief prohibitory clauses of the acts were repealed in 1896, when the development of the internal-combustion engine had opened up entirely new prospects and suggested new possibilities.

Gottlieb Daimler's invention in 1885 of the internal-combustion motor using petroleum spirit was the first step towards the production of the modern self-propelled road vehicle, the next step being the recognition in 1887 of the advantages of Daimler's system by M. Levassor and his application of that system to the propulsion of a carriage. In the nine years that immediately followed French manufacturers spent large sums of money in experimenting with and developing the motor-car, and by 1896, when the Enabling Act was passed, there were a few practical vehicles in England but, perhaps, fewer probable buyers. British makers, starting as they did in the wake of the French manufacturers, were able to profit by the experience gained by the latter, and thus to avoid many otherwise inevitable mistakes; they may not be able to claim to have originated many of the fundamental details of the modern motor-car, but their experience was gained at a comparatively small cost.

Gottlieb Daimler's engine marked a great advance in the production of a source of motive power, for its efficiency was large as compared with its total weight, whilst the simplicity of its fuel system brought it within the scope of the person of average mechanical instincts and intelligence, for, even in its early days, the internal-combustion motor did not demand that its user should possess an intimate knowledge of engineering. Daimler fitted one of his motors to a bicycle in 1885, and afterwards applied the system to the propulsion of boats, one or more of which were running on the river Seine in connexion with the Paris Exhibition of 1887. It was this fact that brought the invention to the notice of M. Levassor, of the Saumur & Levassor, makers of wood-working machinery, who saw the possibilities of its application to the propulsion of a road carriage.

MM. Panhard & Levassor secured the French patents from Daimler, and M. Levassor devised the transmission system which, as far as its general scheme is concerned, is unaltered to-day, despite many efforts on the part of skilful inventors and designers to secure something better. M. Levassor placed the engine in front, the axis of the crank-shaft being parallel with the side members of the frame of the vehicle. The drive was taken through a clutch to a set of reduction gears and thence to a differential gear on a countershaft from which the road wheels were driven by chains. With all the modifications of details, the combination of clutch, gear-box and transmission remains
unaltered, so that to France, in the person of M. Levassor, must be given the honour of having led in the development of the motor-car.

Progress in the improvement of design was slow until the year 1894, when a great impetus was given to the French industry by the organization, by the *Petit Journal*, of a trial run of motor vehicles from Paris to Rouen. The measure of success attained by the cars caused considerable surprise, and in the year 1895 a race was organized from Paris to Bordeaux and back, a distance of 744 m., when the winning vehicle covered the journey at a mean speed of 15 m. per hour. From that date onward, until 1908, racing played an important part in the development of the motor-car; in fact, it is not going too far to say that, up to 1904, it played a vitally important part therein. The effect was a rapid development in speed, efficiency and reliability, and others besides the sportsman and the individual seeking for new sensations were attracted towards the new vehicle. Racing was not indulged in in England or Scotland, the authorities having no power to close the roads for the purpose.

In July 1902, Mr S. F. Edge, driving a 50 h.p. Napier car, won the Gordon-Bennett Cup in the course of the open race from Paris to Vienna. This trophy has played an important part in the history of the motor-car. It was offered for competition among cars, entered by recognized National Automobile Clubs, no more than three cars being permitted to represent a country, and every car had to be built entirely in the country of its origin. The length of the race had to be not less than 500 kilometres (310 m.). The first two races in 1900 and 1901 had been won by French cars and, as these contests had been run concurrently with the big city-to-city races, the importance of the Gordon-Bennett race was overshadowed. But it stood out in bold relief when an English car wrested the international trophy from its French rivals in 1902. The Automobile Club of Great Britain and Ireland (now the Royal Automobile Club) at once secured parliamentary sanction for the use of certain roads in Ireland for a limited period, and proceeded to organize a race worthy of the issue at stake. The race was won by the Médecès car, the latest production of the famous house of Daimler.

The Médecès car set quite a new fashion, for it showed advancement in a large number of its mechanical details, and many of these details were either copied or used as the basis for radical changes in previously-existing designs. So far as British makers were concerned, the Médecès fashion was allowed to predominate, but some of the older French makers were less willing to follow the lead of the great German house. This fact assisted the British makers to forge ahead in their competition with the French. But the great factor in the triumph of British motor engineering arose from the fact that, in England, there was a great wealth of knowledge concerning the properties of steels and steel alloys, and that knowledge, which was advancing all the time, was turned to such good use that it is safe to say that, in only the very best of French cars is the same strength and efficiency obtained from the same weight of metal as would be used in the construction of quite a number of British cars. Lightness of moving parts has led to increased engine efficiency and to economy of fuel, whilst the inert parts of the mechanism—the frame and other fixed details—by being lighter, call for a smaller expenditure of power to overcome their inertia. Apart from the employment of special steels for motor-car construction, in which England took a leading part, many improvements in design and method have originated in Great Britain. For instance, the multiple-disk clutch, which permits a car to be started without shock, is an English invention, as are the detachable wheel, the spare wheel and the six-cylindered engine. The latter, introduced by the Napier Company and employed extensively by them, by Rolls-Royce and others, has exerted a great influence upon British tastes, because it created a growing dislike to noise, one of the consequences being the rapid development of the silent car.

The representatives of Great Britain in the Gordon-Bennett race of 1903 were selected by means of a series of eliminating trials, and in 1904 and 1905 races were held annually in the Isle of Man for the same purpose. In the years 1906, 1907 and 1908 races were held in that island with such limitations on fuel or on the diameter of the cylinders as were calculated to encourage the development of small but efficient transmissions, and it has been conceded generally that these races served an extremely useful purpose.

Concurrently with its development into a reliable, silent, odourless and smokeless power-propelled vehicle, the motor-car gradually came into more general use. It no longer appealed only to a few but gained converts daily, and its final triumph came when it began seriously to displace the horsed vehicle.

**Fig. 3.—The 40-50 h.p. Six-cylinder Rolls-Royce Pullman-Limousine.**
becoming the private carriage of the wealthier classes to be used on all occasions.

If the motor-car in the guise of a private carriage has developed at an astonishing rate, its adaptation to the needs of the community, as a public service vehicle, has been even more rapid. The first cabs placed on the streets of London in 1903 were by no means a success, but the cabs constructed by the French house of Renault and first introduced in London in 1906 rapidly effected a revolutionary change in the means of individual transport. Apart from the improved speed of the motor-cabs, they gained popularity because of the use, on each one of them, of the taximeter, showing at a glance the amount of the fare, thus preventing overcharge on the part of the driver. One effect of the employment of motor-cabs and motor-omnibuses has been to reduce slightly the total number of vehicles, and to quicken a large volume of the traffic; it is now being recognized that to increase the speed of the whole of the traffic of London by about 5 m. an hour is practically equivalent to doubling the width of the whole of the main streets.

The new British act of 1903, which was enacted for three years only, was, during the parliamentary session of 1906 and subsequent sessions, continued from year to year because of the difficulty that was experienced in reconciling conflicting views about the control of motor-cars. The 1903 act raised the speed limit to 20 m. per hour and gave the local government board power to close to motor traffic such roads as, on inquiry, might be deemed unsuited therefor, and to impose a speed limit of 10 m. an hour or less in dangerous places, such as narrow streets in a town or through a village. A few serious accidents in England, and many abroad, have kept alive the fear that the motor-car is a dangerous vehicle that should be restrained or held in check by stringent legislation. Thus from 1904 onwards, the motorist was under continuous police supervision. Police traps were measured distances, over which the motor-car is timed by the police, were established in most of the counties of England, and, whilst, without a doubt, many real offenders were caught, it is equally true that many innocent drivers were unfairly accused, whilst motorists guilty merely of technical infringements of the law were summoned.

The attitude of the police in showing little or no leniency in the application of the law probably, however, did good in other directions, although these were not contemplated either by the law-givers or the police themselves. It considerably limited the use of excessively powerful cars (for example, a 60 or 90 h.p. car that could easily attain 60 m. an hour), and experience has demonstrated the fact that, intersected as England is with a network of narrow roads carrying considerable traffic, there is little opportunity for the full power of such a car to be used. The result has been that the comparatively low-powered vehicle has been developed in efficiency, bringing with it the advantages of economy in running, simplicity of mechanical details, cheapness of maintenance and ease of control and management.

The principle of the internal-combustion engine has not been altered since Daimler's day, but the mechanical details of the engine have undergone constant revision and improvement, until in 1910 it was safe to say that a four-cylindered engine, with a cylinder bore of 4 in., constructed, we will presume, in 1899, might have developed 20 h.p. or less, whereas engines of the same cylinder bore made in 1908 and 1909 actually developed 60 h.p. and more, and the attainment of even greater efficiency was in sight in 1910. Experience showed that the saving of weight meant greater economy in fuel and also in tires, the two principal items in the upkeep of the motor-car. Engine design has undergone unspeakable improvement, the principles of combustion and exhaust systems have been continuously advanced, with the end in view of attaining lightness, not only in the moving parts, but in the inert parts. Lightness in reciprocating parts, such as the pistons, connecting rods and valves, has enormously improved crank-shaft speed. Cylinder castings are now made far lighter, whilst the water jacketing, for dissipating the excess of heat from the cylinder walls, is now of sufficiently ample proportions and, in consequence, better lubrication of the cylinder walls can be maintained. This again conducted to piston speed. The induction valves of engines of the earlier types were opened under atmospheric pressure, the reduced pressure in the cylinder, caused by the downward movement of the piston, enabling the pressure of the outer atmosphere to open the valve against its light spring, and to carry in a charge of the carburetted air that constituted the explosive mixture. But it was found that the automatic or atmospheric inlet valve opened late on the induction stroke and closed early, so that the engine only received an attenuated charge. One of the earliest improvements in engine design, therefore, was the employment of the mechanically-operated inlet valve operated by a cam exactly as the exhaust valve is operated. This valve could be fully opened as soon as the piston had begun its downward or induction stroke, and could be held open during the momentary period when the piston was at rest at the bottom of the stroke, thus ensuring a full charge of explosive mixture. The method of exploding the charge in the cylinder has undergone revolutionary changes. The first method, that of heating the exterior of a closed tube connected with the cylinder, quickly gave way to electric ignition because it was found that the charges could not be exploded by the hot tube until the piston had reached the top of its stroke, and, at the comparatively low piston speed of these engines, the piston had moved some distance on its downward stroke before the exploded gas had begun to expand. Electric ignition was an improvement because it enabled a “lead” to be given to the explosion, a low voltage current (from four to six volts of about one amperes being sufficient for the purpose) being automatically switched on to the primary circuit of a coil, the induced current in the secondary circuit being of a voltage sufficiently high (calculated at from 5000 to 10,000 volts of a very small amperage) to jump across a gap left in a sparking plug inserted in the cylinder. By rotating the body of the switch (called the contact breaker) the ignition could be timed to suit exactly the speed of the piston and, in this way, greater piston speed was obtainable. The great development of this system was the introduction by Mr F. R. Simms, in conjunction with Herr Bosch, of the magneto machine, known as the Simms-Bosch magneto, the prototype for many such appliances. This machine, in its simplest elements, produces a low voltage current (assumed to be of about eight or ten volts) by the rotation of an armature in the magnetic field of a set of magnets, the rotation being effected through the timing-gear wheels of the engine. The low tension current is conveyed through a primary circuit inducing the secondary current which is employed for igniting the charges. The advantages of the magneto are, firstly, that the primary current is created by the engine, and that the need for an accumulator as a source of that current is avoided and, secondly, that the spark is more efficient because the faster the armature is revolved the more intense is the primary current and the induced current, consequently, the charge is ignited more rapidly. The magneto machine has almost entirely displaced the accumulator system for ordinary running, although, as the latter makes for easier starting, it is often fitted as an addition.

Great gain in power has been secured from improvements in the lubrication of the internal-combustion engine. It is now recognized that a small supply of oil to the journals and bearings of such an engine is insufficient, but in the early days it was found difficult to give the journals and bearings more oil without much getting on to the cylinder walls, because the latter were lubricated by the oil that was thrown on to them by the spinning action of the webs of the crank-shaft and by the connecting-rod ends, these latter dipping into a well of oil in the lower part of the crank-chamber. This made it necessary to overcome this difficulty. The cranks and connecting-rod ends no longer dip into the oil, for the latter drains away into a sump or reservoir below the base of the crank chamber. Thence it is passed through a filter and pumped to ducts which convey the oil under pressure to the crank-shaft journals. Sometimes it is conducted thence along ducts bored in the crank-shaft and
through the webs and crank-pins, whence it feeds the connecting-rod bearings, enough squirting out to splash on to the cylinder walls. Sometimes, a shallow trough is placed under each connecting-rod end, to hold oil to a certain depth and no more, and a scoop on the big end collects enough oil to effect the lubrication of the connecting-rod bearings and cylinder walls. The aim has been to secure definite lubrication of all moving parts, and, at the same time, to prevent oil being present on the cylinder walls in such quantities as will permit the piston to carry it up into the combustion chamber. Any oil present in the combustion chamber is burnt during the explosion, but, its combustion being imperfect, smokiness of the exhaust is the result. By reducing the oil on the cylinder walls to the minimum necessary for lubrication, smoking has been abolished, whilst clogging, or carbonizing, of the valves has been materially reduced.

Methods of carburation have also undergone improvement, so that the carburation shall not materially vary with varying engine speed. The only other feature in the engine that calls for mention is the method of cooling. With the introduction of the honeycomb type of radiator, by which the water is made to flow through canals an eighth or a sixteenth of an inch wide, the efficiency of the cooling system has been doubled because of the large amount of surface, in a given size of radiator, for dissipating the heat. A fan is generally employed, either situated behind the radiator and driven by the engine, or the flywheel is vaned so as to induce a current of air through the radiator.

To deal now with the transmission mechanism, the drive is taken through a clutch and gear-box as in the earliest days, but, for the final drive, chain transmission to the road wheels running on a fixed axle has largely given place to propeller drive on to a live axle. The leather-faced conical clutch, although still employed, has in many cases given way to the multiple-disk clutch in which a number of disks bearing against each other, either flat in section, or (as in the Hele-Shaw clutch) having annular tapered grooves, are contained in an oil-tight box. These plates are capable of being separated laterally from each other when "out of gear," or brought into frictional contact with each other when it is desired to start the car. Metal-to-metal cone clutches, expanding metal shoe clutches, single metal plate clutches and coil spring clutches have all at some time found favour with designers wishing to avoid a leather clutch. Hydraulic and electro-magnetic clutches have also been tried, but these have not gained any vogue. In the matter of the gear-box, the sliding into mesh of the gear-wheels as employed by Levassor is still the standard practice, although that pioneer himself regarded the method as barbarous, and looked upon it as a mere temporary expedient. But details of the gear-box have materially improved. A single lever is usually employed for engaging any of the forward gears or the reverse, so that the mistake of simultaneously engaging a reverse and a forward gear is not possible. The spur-wheels are generally mounted in pairs on two sleeves, so that, by means of a selector mechanism that compels one sleeve to be brought to the neutral position before the other can be moved, no two gears can ever be engaged together. By means of "dog clutches," the clutch shaft can generally be coupled direct with the bevel-wheel driving the back axle, the "drive" on the highest gear being thus transmitted without passing through any spur-wheels. This reduces noise and frictival losses. Except for cars of great weight, chain transmission is fast dying out, the power being generally transmitted through a propeller shaft (with universal joints at one or both ends) to a bevel-drive on the back axle; such axle being divided into two revolving or "live" axles carrying the differential gear between them. The bevel-wheels, differential gear and live axles are enclosed and run in a lubricant.

Wire suspension wheels are growing considerably in favour, a saving in weight being thus effected. The liability of the pneumatic tire to deflation, through a puncture or burst,
has led to the introduction of detachable rims and detachable wheels. The detachable rim is borne on the periphery of the wheel (which is bonded) and secured in position by various methods. When the tire is punctured or damaged the rim and tire are removed bodily and replaced by a spare rim with its tire already in position and inflated, a change capable of being effected in five minutes or less. The detachable wheel is mounted upon a shell which fits over and is secured to a sleeve, which latter turns and is secured upon the fixed axle. In the case of tire trouble, the wheel intact is removed from the sleeve (which in the case of a driving-wheels carries the driving fittings, the brake-drums, &c.) and a duplicate wheel is substituted. The pneumatic tire has undergone continuous improvement, particularly in the matters of the selection of the material and the proportioning of the strength of the “body” to the work which the tire is to be called upon to perform. Various methods have been devised for the prevention of skidding or “side-slip” on greasy surfaces, and, whilst certain mouldings on the rubber treads have proved advantageous, the method most adopted is that in which a large number of steel studs stand about a quarter of an inch above the surface of the tire.

It will be seen that the general lines of the car of 1899 have not required to be radically altered. Every detail has been improved so that the cars are more efficient, easier to control and manage, and infinitely more comfortable, but, in essence, Levasseur’s scheme is as good to-day as it was when planned by him.

The steam car is made by five or six British manufacturers at the worst, whereas the actual manufacturers of petrol cars in Great Britain numbered at the end of the year 1909 about seventy, whilst some four hundred other firms were actively engaged in the construction of cars and their parts, accessories and sundries. But the steam car appeals to those men who are or have been steam engineers, and to them the management of the steam generator and the burners constitutes no difficulty. The limitations under which the early steam car laboured have, in the main, disappeared, for the modern steam car can travel nearly as far without requiring to refill the boiler as a petrol car can travel without replenishment of the fuel tank. The electric car is still the luxury to be employed in towns and in covering short distances, for the weight of the accumulators has not been greatly reduced, despite sensational announcements made from time to time.

An interesting feature of the motor movement has been the steady growth in popularity of the motor cycle. The motor triycle was developed up to the year 1903, and then gradually became displaced by the motor bicycle, which had been introduced in 1901. Motor bicycles gradually increased in popularity, until in numbers they were in excess of cars. The standard machines of 1909 had an air-cooled motor of one, two or even four cylinders (according to the choice of the riders) developing some 3 to 8 h.p. with magneto ignition and belt drive. The engine was usually started by the rider running alongside the machine, and causing the machine to rotate the crank-shaft through the belt and pulley until the initial explosion was obtained, when he would jump into the seat. Trailers were employed at first for carrying passengers, but, the length of the combined vehicle being between nine and ten feet, a side-car, placed at the side of the cycle and secured thereto by detachable fittings, largely displaced the trailer and also the “fore-car,” in which the passenger was carried in a body placed in front of three- and four-wheeled cycles.

The rapid growth of the motor movement in Great Britain may be judged from the fact that by the 30th of September 1905 the number of motor vehicles of all kinds registered had totalled 74,038, and by the 30th of September 1906, three years afterwards, to 90,415. Of these, 137,323 were registered in England and Wales, 10,907 in Scotland, and 6,265 in Ireland. 71,405 were private motor-cars; 12,104 were trade motor-cars; 5880 were public service vehicles and 65,026 were motor cycles.

A year later (Sept. 30, 1906) the figures showed a further remarkable increase, the total number of vehicles registered in the United Kingdom being 183,773, giving an increase of 29,358 in the year. Of these, private motor-cars numbered 84,840; trade motor-cars 15,181; public service vehicles 8752; and motor cycles 75,000. The numbers registered in England and Wales were 74,748 private motor-cars; 13,961 trade motor-cars; 8131 public service vehicles and 66,341 motor cycles, or 163,181 in all. The figures for Scotland were: 6157 private motor-cars; 1056 trade motor-cars; 584 public service vehicles and 3363 motor cycles or 13,003 in all.

The figures for Ireland were: 3935 private motor-cars; 164 trade motor-cars; 37 public service vehicles and 3363 motor cycles, or 7499 in all. In the year private motor-cars in the United Kingdom increased by 18-8%; trade motor-cars by 25-4%; public service vehicles by 48-8% and motor-cycles by 15-3%.

It is possible to obtain a better idea of the number of motor vehicles in use from the returns of the commissioners of inland revenue. The total number of privately-owned cars for which licences were issued in 1908 was 48,019, of motor cycles 35,784, and of motor-driven hackney carriages 17,300. These figures may be compared with the registration figures already given for the year ending the 30th of September 1906. As the former was prepared partly for the difference, a certain proportion of the registered vehicles (seeing that the figures include all vehicles in use on and after the 1st of January 1904, less those in respect of which the registrations have been cancelled) must have fallen into disuse and some vehicles will have been sold out of the country, whilst others will have been re-registered with different authorities. But the life of the mechanism of a car, in one form or another, is of considerable length (there were, for instance, in use in 1910, as commercial vehicles, motor chassis that were put on the road in 1896), and it is considered that many registered but unlicensed cars remain for years capable of rendering useful service in emergencies or on special occasions, such as at election periods.

In 1906 an act of parliament authorized a census of production, which was taken in 1908, the statistics relating to 1907. These figures show that the output of complete motor vehicles in the United Kingdom in that year was 11,790 completed cars and chassis, and 3600 motor cycles, the total value of the productive work.
In 1910, 45% of the total consisted of motor cycles, 49.3% consisted of pleasure vehicles and 5.7% consisted of commercial vehicles, the proportion of pleasure vehicles having consistently risen in the four years.

The development of motoring and of the motor industry in the United States has been exceedingly rapid. As good roads multiply and extend the use of cars must be still further developed. The American farmer has discovered that he can make considerable use of the motor-car in connexion with his industry, and this fact largely accounts for the demand for high-wheeled buggies, and for vehicles having ample clearance between the machinery and the road level.

In the early days of the movement the American taste inclined towards steam cars and the improved type of motor car driven by an internal-combustion engine could never be made to run as silently as a steam car was generally held. But in Europe the petrol engine became refined so rapidly that its equality with the steam engine in the eyes of the largest number of people has been obtained in the matter of simplicity and suitability for the man who is not an engineer, soon created for it a popularity that prevented any material expansion of the business in steam cars. The makers of steam cars in America are able to cope with the major portion of the market for this particular type of vehicle.

The introduction of the Dingley tariff, assessing an import duty of 45% ad valorem on motor-cars (in the classification of "manufactured metal"), added to a further charge of about 5% ad valorem, had a great effect upon the business of the manufacture of motor-cars, and in 1899 thirty manufacturers produced 600 cars. In 1909 the number produced by 200 concerns was 114,891. Set out in tabular form such figures as are obtainable are very striking:

The number of cars in 1906 is approximately and the number of cars and their value for the year 1910 are based upon the estimated output of the various manufacturers. In 1908, whilst the number of cars constructed showed an increase over the number for 1907, the total value had decreased owing to the commercial crisis of that year.

The second major manufacturer was the American Association of Licensed Automobile Manufacturers, and who agreed to recognize the validity of the Selden patents, paid licence fees upon 94,891 cars, the remaining 20,000 cars being estimated as the output of the concerns that did not belong to the Association.

Of the 200,000 motor vehicles estimated to be constructed in 1910, 165,000 were to be petrol-driven pleasure cars, 30,000 were to be petrol-driven high-wheeled buggies, and 5000 steam and electric carriages and commercial vehicles.

The history of the Selden patent may be given briefly. A patent was applied for on the 8th of May 1879 by George B. Selden, of Rochester, New York, for a gas compression engine for propelling road vehicles. A patent was granted to him on the 5th of November 1885; for an improvement in road engines he claimed that any vehicle propelled by an internal-combustion engine, manufactured since that time, was an infringement of his rights under the patent. At the commencement of the year 1910, 71 manufacturers admitted this claim and paid into the Association of Licensed Automobile Manufacturers 13½% of the catalogue price of their products as licence fees.

The imports of motor vehicles into the United States of America are not numerous, as will be seen from the following figures:

The exports rose from $59,000 in value in the year 1902 to $5,902,411 in 1906, falling off to $5,277,847 in 1908.

run, on an average basis of 180 m. a. week; with a trailer carrying another 3 tons the corresponding figures vary from 9d. to 1s. per mile run, according to nature of roads, gradients and fuel available. The inclusive working cost of a tractor, on macadamized roads, is generally about 15% less than for a 5-ton wagon, but a standard tractor cannot haul more than a gross load of 8 tons behind the drawbar—except on dry and level roads. On granite sets the extra vibration often causes undue wear and tear, unless the suspension of the tractor be very good.

Vehicles in which the power is derived from internal-combustion engines are commonly known as "petrol" vehicles. Petroleum spirit of 0-700 specific gravity is usually the fuel, but many are now supplied with spirit of 0-760 specific gravity; the range of boiling points is the criterion of satisfactory use—not the density. Petrol vehicles are, practically, stoutly-built motor-cars, and some of the models now in use have been developed from accepted designs of lighter types. There are, however, numerous manufacturers who construct solely for utility purposes.

has a virtual monopoly of use in England; above that, it shares the trade with steam. A tabular statement of current working costs of approved petrol vehicles is published herewith.

Before proceeding to describe and illustrate representative types of vehicles, tractors and special machines, a brief summary of the outstanding points in the English statutes and orders which apply to heavy motor-cars may well be given. Any motor-car with an unladen weight in excess of 2 tons is held to be a "heavy motor-car," and a "trailer" means a vehicle drawn by a heavy motor-car. The expression "axle weight" means the aggregate weight transmitted to the surface of the road or other base whereon the heavy motor-car or the trailer moves or rests by the severally wheels attached to that axle when the heavy motor-car or trailer is loaded. The expression "weight," in relation to a heavy motor-car or trailer when unladen, means the weight exclusive of the weight of any water, fuel or accumulators used for the purpose of propulsion.

All heavy motor-cars have to be registered with a county council, or other registering authority, and owners have to declare, on suitable forms, the unladen weight, the axle weight of each axle, and the diameter of each wheel. When a registration certificate is issued it bears these data, in addition to a statement of the width and the material of the tyre on each wheel, and the highest rate of speed at which the heavy motor-car may be driven. The owner, after registration, must cause to be painted, or otherwise plainly marked, upon some conspicuous part of the offside of the heavy motor-car, the registered weight unladen, and the registered axle weight of each axle, whilst, upon the near side of the heavy motor-car, must similarly cause to be painted the highest rate of speed at which it may travel. Width of tires, which in no case may be less than 5 in., varies in relation to imposed load and wheel diameter, and a table of these is issued by the local government board. It is specified that "the width shall not be less than that
number of half-inches which is equal to the number of units of registered axle weight of the axle to which the wheel is attached." Taking a wheel 3 ft. in diameter as a basis, the unit of registered axle weight is 2 \( \frac{3}{4} \) cwt.; this unit increases in the proportion of 1 cwt. per 12 in. increase of diameter, and decreases at the rate of 1 cwt. for every 6 in. reduction in diameter below 3 ft. The speeds at which heavy motor-cars may travel vary from 5 m. an hour to 12 m. an hour. Heavy motor-cars fitted with tires of a soft or elastic material may travel at higher rates of speed than if they were not so fitted. Any motor-car used for trade purposes, but whose unladen weight does not exceed 2 tons, is allowed to travel as fast as 20 m. an hour, and is regarded as an ordinary motor-car.

**Motor-buses.**—The first double-deck motor-bus, of the type of which upwards of 1000 are in regular service in London, was licensed by the police authorities in September of 1904. The type of chassis employed is practically identical with those used for loads of 3 tons in the goods-haulage branches of the industry, and the accompanying chart, which is prepared from data exclusively collected by the Commercial Motor (London), indicates the growth in the totals since the inception of this departure in the public conveyance of passengers. The growth of motor-bus traffic has resulted in the displacement of some 25,000 horses and 2200 horse omnibuses, during the five years ending the 30th of June 1910, and it is estimated that there will be practically no horse omnibuses in London, except upon a few suburban routes, by the end of 1911. The inclusive working cost of a London motor-bus, with good management, varies between 9d. and 10d. per mile, which figures cover interest, depreciation and administration.

Successful provincial motor-bus undertakings, in the United Kingdom, are numerous, and those at Eastbourne, Keighley and Hull may be particularly mentioned of municipal undertakings, whilst the Great Western Railway Company alone has 130 such vehicles at work.

**Motor-cabs.**—Spasmodic efforts to introduce motor-cabs in London were made during the years 1905 and 1906. It was, however, only in the month of March 1907 that the General Motor-cab Company put the first 100 vehicles of its present large fleet into regular service. The growth of motor-cabs is indicated by the following numbers, for which the author is indebted to the Commercial Motor (London), and these are of vehicles licensed at the dates given: December 31, 1905, 10; December 31, 1906, 96; December 31, 1907, 723; December 31, 1908, 2805; April 30, 1909, 3203; April 30, 1910, 4941. It is estimated that, at the 30th of June 1910, there are only 1200 horse-drawn hansom cabs in regular use, and not more than 2500 horse-drawn four-wheelers, in London. In 1904 London had a total of 11,555 horse-drawn hackney carriages, and two self-propelled hackney carriages. The London hiring rate for motor-cabs fitted with taximeters is: for the first mile or part thereof, 8d., subject to an additional charge at the rate of 2d. per 1/2 minute for any waiting time or travelling below the rate of 6 m. per hour; 2d. per additional 440 yds., or 1/2 minute of waiting or of travelling below 6 m. an hour; with the addition of 2d. per package for any package carried outside, and 6d. for a bicycle and 6d. each for each passenger above two, for any distance. The horse-drawn hansom-cab is 1s. for the first 2 m., with 6d. for each additional mile or part of a mile, and with a charge of 8d. per 15 minutes of waiting, after the first 15 minutes completed. Taximeter cabs cannot be engaged by time in London, but horse-drawn cabs may be so engaged at 2s. 6d. per hour for a hansom, and at 2s. per hour for a four-wheeler. The taximeter rates apply throughout the Metropolitan Police area, which in some directions extends as far as 20 m. from Charing Cross, but horse-vehicle rates except those of time) are doubled for any distance beyond a four-mile radius.

**Steam Vehicles.**—Steam wagons may, generally speaking, now be divided into three distinct types, and these are distinguished chiefly by the particular form of final drive adopted by the designer. There are in general use by the well-known

---

Figs. 6-9.—Standard and Representative Types of Present-day Steam-wagon Construction.
MOTOR VEHICLES

The transmission on the first type of vehicle (figs. 6 and 7) is by means of gearing throughout, and is completely enclosed, thus ensuring protection from dust, and more perfect lubrication. Change gears to give two speeds are provided. This form of drive necessitates a special disposition of the spring mounting, in order to ensure that there shall be no sliding motion taking place between the teeth of the reducing gear, due to the distance between the centres of the countershaft and the back axle varying with the changes in the spring deflexion. The gear drive offers advantages which, for heavy loads, are not offered by any other form of drive.

The features which are common to all steam wagons of the second of these types are: vertical fire-tube or water-tube boiler; horizontal compound engine; two-speed gear; differential countershaft; and two sprockets which transmit the final drive, through chains, to the rear road wheels. The exact form which the boiler takes is a point which has considerably exercised the ingenuity of individual designers, in order to arrive at one that can be cheaply produced.

FIG. 10.—The Unique Type of Steam Wagon made by the Yorkshire Patent Steam Wagon Co.

is the outcome of many years' experience in the design of road locomotives, on the lines of which it is constructed. The locomotive type of boiler is very economical in fuel consumption, and is a very efficient steamer. Comparing this type of boiler with the vertical type, the former can be made of a much lighter construction for a given rate of evaporation, and the smoke-box door at the forward end offers a most simple and easy means of access to the smoke tubes for cleaning purposes. No vertical boiler offers such ready means of effecting this operation. The engine, which is mounted over the boiler in this type, is in full view of the driver, and, should it become necessary to make any repair or adjustment when on the road, this can easily be effected without grovelling under the wagon or removing any of the load. Objection may be raised to the position of the engine, on the score of its necessitating such a long chain drive to the back axle; this objection has not been sustained in practice, as many wagons employing this form of drive have been running for lengthy periods without giving any trouble on that score. The engine, which is a compound one, is close up to the source from whence it is supplied with steam, and consequently receives the steam in a much drier condition; there is less condensation in the main steam-pipe, because the length of this is reduced to a minimum. The short steam-pipes should tend to lessen the risk of their being broken from the sagging or twisting of the frame, a fault which is not unknown with vehicles having the engine a considerable distance from the boiler. This type, like types 1 and 2, also has two change-speed pinions, mounted on an intermediate shaft. These pinions may be of the sliding type, or may be operated by means of dog-clutches. The pinions mesh with two wheels that are mounted on a countershaft, on which is also fixed a chain-sprocket, from which the drive is transmitted, through a long chain, to a chain-wheel surrounding the differential gear mounted on the back axle. Traction-engine type of steering gear, with revolving fore-carriage, is most generally adopted, and is rendered sufficiently rapid in its movement by suitable gear, operated by a diagonal shaft and wheel, from the driver's footplate.

Fig. 10 shows the general disposition of the main parts of a "Yorkshire" steam-wagon. This machine follows the general lines of those of type 3, so far as transmission gearing is concerned, but its boiler is of very distinctive construction, as may be seen from the sectional view in fig. 11: its engine is one of the vertical compound type, and is mounted directly behind the driver.

FIG. 11.—The Yorkshire Steam Wagon Co.'s ingenious Loco-type Transverse Boiler.

The Shepppee steam-wagon, or "steam-gas" vehicle as it is sometimes termed, on account of the high degree of superheat to which the steam is raised, and which superheat gives to the steam many of the characteristics of gas, is shown in fig. 24, and, it may be seen this wagon is entirely dissimilar to any other machine with which this article deals. The generator and paraffin burner are housed within a "bonnet," and the temperature of the steam is controlled by a very simple form of thermostat. After leaving the engine, some of the heat in the exhaust steam is utilized to heat up the feed water before it is passed into the generator; the steam then passes in series through two condensers—one in front and one underneath the vehicle.

Another vehicle which embodies many novel and practical features is the new Leyland steamer, the construction of which includes one of the well-known Leyland fire-tube boilers, as shown
in fig. 18, a three-cylinder, single-acting, vertical engine, and an all-gear drive to the rear wheels.

**Boilers.**—The locomotive type of boiler is shown diagrammatically in figs. 12-15. The first of these four diagrams illustrates the type of heat provided in the mass of the heated tubes, and the rapidity of flame application by the burner, and not in a mass of heated water. The steam, too, is very highly superheated, and necessitates the use of a specially-designed engine with mushroom valves.

**Figs. 12-15.**—Fig. 12 shows the Belpaire type of fire-box construction as compared with the more usual type shown in fig. 13. Fig. 14 and fig. 15 show the form of locomotive boiler fitted by Sidney Straker & Squire, Ltd. The back of the fire-box is sloped so as to accommodate the gear shafts without unduly lengthening the frame.

Belpaire type of fire-box outer shell, and, by its side fig. 13 shows the older form of construction. The Belpaire fire-box is a development of recent years, and its undoubted superiority over the older type is meeting with increasing recognition amongst boiler makers. The sloping back plates of the fire-box, as shown in fig. 15, are intended to give plenty of room for the housing of the change-speed gearing without undue lengthening of the vehicle or reduction of the area of the fire-grate.

**Figs. 16, 17, 18.**—Fig. 16 shows the Toward Vertical Boiler, fig. 17 Alley & MacLellan's Sentinel Water-tube Boiler, and fig. 18 the Vertical Smoke-tube Boiler fitted on Leyland Steam Wagons. The smoke tubes in the last-named boiler are provided with copper sleeves to prevent corrosion.

Figs. 16, 17 and 18 show vertical boilers made, respectively, by Toward, of Newcastle, Alley & MacLellan, of Glasgow, and the Leyland Co., of Leyland. The smoke tubes of the last-named boiler are provided with copper sleeves, the object of which is the prevention of corrosion of the outer surfaces of the tubes. All-copper tubes have been tried, but they are too soft to withstand the abrasive action of the fine particles of coke which are ejected from the fire.

In flash or semi-flash boilers, or steam generators, such as are fitted by the Darracq-Serpollet Co., the Sheppey Motor Co., of York, and to the tractor made to the designs of Colonel Crompton, C.B., (fig. 26), only a very small volume of water is at any time in the tubes. The tubes are exceptionally strong and thick, and they are made of cold-drawn steel; the water is only forced into them stroke for stroke of the engine. The essential difference between this class of generator and any ordinary motor-wagon boiler, whether of the water-tube or fire-tube patterns, is that the reserve

**Fig. 19.**—The Lune Valley Paraffin Burner.
with an engine of this type it was found possible to work it on an expenditure of 13 lb of water per brake-horse-power hour. Another interesting superheated steam engine is the two-

type does not necessitate the fitting of eccentrics; the second system entails the use of one eccentric for each cylinder; whilst Stephenson's system necessitates the provision of two eccentrics per cylinder.

---

**Fig. 20.**—The Bentley Eight-cylinder Diagonal cylinder, double-acting engine made by the Sheppey Co., and illustrated in fig. 21. In this engine the cam-shaft by which the steam and exhaust valves are operated is situated midway of the cylinders' length, and is driven by bevel gearing from the crank-shaft. Fig. 22 shows a combined steam and hand-operated water pump, for use in conjunction with either of the engines mentioned.

**Fig. 21.**—The Sheppey Motor Co.'s compact Double-acting Superheated “Steam-gas” Engine.

The Sentinel wagon, built by Alley & MacLellan, Ltd., is perhaps the only heavy steam wagon with a two-cylinder, simple, double-acting engine controlled by cam-actuated poppet valves; this engine is shown in section in fig. 23, and, in some respects, it greatly resembles the Sheppey engine. The four special engines already named—those by Leyland, Bentley, Sheppey and Alley & MacLellan—differ totally from the type which is fitted most usually on steam-propelled commercial motors, yet they are very practical examples of special practice. The majority of steam vehicles are provided with two-cylinder compound engines, in which the steam distribution is effected and controlled by one or other of the proved link motions, such as the Joy, the Solms or the Stephenson. The first-named

---

**Fig. 22.**—The Sheppey Combined Steam-driven or Hand-operated Water-pump.

Steam Tractors.—The great popularity which the light steam tractor enjoys is undoubtedly due to its extreme usefulness in cases where the employment of steam wagons could not prove remunerative. For brickmakers, builders, market gardeners and a host of others whose business demands that separate loads of heavy material must be moved from place to place without involving terminal delays, the tractor offers a simple and ready means of attaining the desired end. The first cost is comparatively low, and such a “steam horse” can be kept constantly at work if there is sufficient demand. A steam tractor is economical and efficient; it can be used on roads where a steam wagon would be impracticable on account of its

---

**Fig. 23.**—Tandem-compound Superheated-Steam Engine.

great axle weight, and, when not used for hauling, it can be put to other work such as driving pumps or builders' machinery, or for a host of other purposes requiring a portable power installation. The fact that the motor is separate from the wagon, or trailer, which conveys the load, and can haul a loaded trailer to its destination, leave it, and return with, or for, another loaded trailer, without waiting for the first load to be unshipped, not only makes this class of motor extremely useful to agriculturists and others, but it makes for greater efficiency, in a large number of cases, because the power unit is not allowed to stand idle during the loading or unloading operations. Another vital point is the low annual cost of maintenance.

Since the passing of the 1903 Motor Car Act, and the coming into force of the 1904 Heavy Motor Car Order, many of the well-known makers of road locomotives have turned their attention to the production of a machine which would come within the prescribed constructional limits, and would meet popular demand. These machines are built on proved traction-engine lines, but with all the parts of suitably reduced size so far as is consistent with strength and the work which the machines are
called upon to perform. The locomotive type of boiler, with large fire-box, a heating surface of about 65 sq. ft., and a grate area of some 3 sq. ft., is used by the leading makers.

Some of the early tractors were fitted with single-cylinder engines, but, although this type is still supplied by several makers, the more general practice is to provide a compound engine, with a multiplying valve which admits high-pressure steam into the low-pressure cylinder, thus enabling the engine to develop considerably more than its normal power for short periods. The engine is mounted over the boiler, with its crankshaft at right angles to the axis of the barrel. Two changes of gear ratio are usually provided; one for normal running, and a lower one for very soft ground or steep hills. The driving axle is of the differential or live type, and provided with means for locking the compensating gear and rendering it inoperative when necessary, as would be the case if one driving-wheel were on hard ground and the other one on soft or greasy ground. A winding-drum is fitted, and this may be driven by the engine without, at the same time, driving the tractor: this result is attained by making the drum free on the axle but providing means of securely locking it thereto when desired. A flywheel generally fitted to one end of the crank-shaft, and this may be used for driving external machinery.

Many makers have recently given much attention to the improvement of the spring-suspension systems of their respective machines, and chief amongst these is William Foster & Co., Ltd., of Lincoln, in which company's "Wellington" tractors the effective spring base has been so vastly increased that it may safely be termed the most stable of steam tractors. The life of all the working parts of a tractor may be considerably lengthened by the elimination of road shocks, or the prevention of their transmission, through the gearing, to the engine and the boiler plates. Foster's tractor is illustrated, in diagrammatic form, in fig. 25.

An ingenious machine of the tractor class is that built to the designs of Colonel Crompton, and shown in fig. 26. This machine is intended for military purposes, or for operation in undeveloped countries. Steam is generated in a "semi-flash" boiler, and is used expansively in a four-pair, diagonal-compound engine of the type shown in fig. 20. A two-speed epicyclic gear is enclosed by the flywheel casing, and the power is then transmitted, by worm gearing, to a differential countershaft, and from sprockets on the ends of this shaft the drive is finally transmitted to the 7 ft. diameter road wheels by means of side chains. In this tractor, very long bearing springs are employed, and these are situated below the axle, so that, instead of the springs resting on the axle boxes, the whole frame and the power plant is suspended from the axle boxes. When hauling a load, the winding cable is permanently secured to the drawbar, and, when the machine becomes "bogged" or is otherwise unable to haul its trailer directly by the drawbar, a single bolt may readily be removed from the drawbar, and the winding cable may then be paid out as the tractor proceeds alone. The trailer may then be hauled up by means of the cable. The average of a number of tests with this machine, made while hauling a gross load of 8 tons, showed that its burners consumed from 65 to 85 of a gallon of shale oil for each mile travelled, and that the consumption of water was at the rate of 5 gallon per mile. The gross weight of the machine, with sufficient fuel and water for well over 100 m. of running, is about 7 tons.

Vehicles Driven by Internal-Combustion Engines.—The general principles of the working of a steam engine are better understood than those of the gas or oil engine, owing to the wide use of the former class of prime mover since the early part of last century, but it is beginning to dawn upon the public at large that the internal-combustion engine, or the "petrol" motor, as it is more popularly termed by those who talk or write about motor vehicles, is even more simple than the steam engine.

The fundamental reason for the use of the words "internal combustion" is that the fuel, in the case of the petrol engine, is burnt (or fired) inside the working cylinder, whereas it is burnt externally in the case of a steam engine, i.e. underneath the boiler or generator. The number of units of heat which can be turned into useful work is very much greater in the case of internal combustion than of external combustion, the efficiency of the petrol engine in this respect being, on the average, about three times as great in practice as is found to be the case with typical steam engines other than those where highly-superheated
steam is used, and where the whole of the parts are maintained in the best condition. The amount of petroleum spirit, or of paraffin, required to propel a steam vehicle 1 m. would, under other conditions being equal, propel a vehicle fitted with an internal-combustion engine over a distance of 3 m.

The essential parts of any internal-combustion system are: the carburettor, the engine, the radiator, the clutch, the change-speed gears and the final transmission. The carburettor is a vessel in which the liquid fuel is converted into a combustible gas or vapour, for, as there is no connexion to any gas main, the ordinary petrol engine has to make its gas “on the premises.” The production of the gas is automatic, and calls for practically no attention from the driver, because, once the engine is started, the necessary aspiration to draw through the correct quantities of air and fuel is provided by the action of the valves and pistons.

A smart turn of the starting handle is required to set the pistons and crankshaft in motion, so that an initial supply of the combustible mixture may reach one of the cylinders. This first charge of gas is automatically ignited by an electric spark, the current for which is furnished and controlled without the necessity for any hand regulation, and there is then nothing further for the driver to do, as regards power, except to move a convenient lever which opens or closes a “throttle” valve between the cylinders and the carburettor.

An internal-combustion engine would get very hot if no precaution were taken to cool it, and it is usual to surround the cylinder with water spaces. These spaces are called jackets, and the water is forced through them, either by a pump or by thermo-siphon (natural circulation) action. It is expedient to keep down the weight of water, and for that reason pipes, tubes or small boxes are built up in such a manner that a large cooling surface is exposed to the air. A fan, which is driven from the crankshaft of the engine by gear or a belt, is employed to aid this cooling by reason of the increased volume of air that passes round the outside of the components of the radiator members. The general scheme is the same, both for heavy and light motor-cars.

It is very important that the driver should have a convenient means of separating the engine from the driving mechanism, and of putting the two in connexion again, whenever it becomes necessary, without jar or shock. The common practice is to use a leather-faced, circular member with a coned face, and to control the amount of “grip” between this member and a corresponding enclosing member attached to the engine fly-wheel by means of a pedal and springs. When the driver wishes to disengage the two members, he has merely to depress the foot lever. It will be clear that a clutch of this description can be made to engage without any difficulty, there being no fixed positions or steps such as one associates with the ordinary jaw-clutch, and this gradual application of the load can only be accomplished by the aid of two or more surfaces in frictional contact, and by the holding together of these surfaces by the pressure of one or more strong springs. The Hele-Shaw multiple-disk clutch gives very good results, and is easy for drivers to use in traffic.

An internal-combustion engine cannot develop power unless the crank-shaft can rotate at a relatively high number of revolutions, and the rate of doing work is lowest when the angular velocity is at its minimum. It is, therefore, necessary to introduce a system of levers between the engine and the road wheels, in order to permit the number of revolutions of the crankshaft to be maintained when hill climbing, or when the vehicle is carrying a heavy load, and the common practice is to introduce three or four sets of different sizes of toothed wheels, any pair of which can be put into engagement by the movement of a single lever, which lever is placed near the driver’s right hand as a rule. The lowest of these gear ratios, i.e. the one which allows the crankshaft to make the greatest number of revolutions to one revolution of the road wheels, is required for starting purposes, and the highest gear ratio, i.e. the one which allows the road wheels to make the greatest number of revolutions in relation to those of the crankshaft, is employed for high-speed travelling on the road. From the last change-speed shaft the power must be transmitted to the road wheels through a differential gear and through one or other of the types of final drive which are now employed by representative makers. The gear which comes from the axles of a horse-drawn vehicle is that there must be both a mechanical connexion, yet a differential action, between the two back wheels. The wheels on horse vehicles revolve loosely on the axle, and one can overrun the other at curves, but the special device known as the “differential gear” has to be introduced into all motor vehicles between the change-speed gears and the driven road wheels. Such a device permits one of the two driving wheels to be driven round at a quicker angular speed than the other, the difference being determined by the radius of the curve around which the vehicle is turning.

The most common form of final drive is, perhaps, that in which two “roller” or “silent” chains transmit the power from

HEAVY MOTOR VEHICLES

927
sprockets on the ends of the differential shaft to chain rings which are bolted to the rear road wheels. Figs. 27, 28 and 29 show typical vehicles, ranging in load capacity from 30 cwt. to 6 tons, on which the side-chain method of final drive is adopted. One of the chief advantages of the side-chain drive lies in the fact that there is, with it, less weight below the springs than with any other form of final drive. The only parts below the springs are: the fixed back axle; the chain rings (bolted to the road wheels); the road wheels themselves; the road-wheel brakes and part of the weight of the chains. The differential gear and chain sprockets are carried in a countershaft casing, which is securely bolted to the main frame.

In a number of very successful vehicles the final drive is transmitted by means of spur pinions. These are mounted on the ends of bevel-driven differential shaft, and mesh with internally toothed or externally-toothed gear rings on the road wheels. Milnes-Daimler and De Dion commercial vehicles are amongst the machines on which the internally-toothed form of gear is employed, whilst Ryknield is the most representative vehicle embodying the externally-toothed form of final drive. The direct drive, from the ends of the differential shaft, as is shown in fig. 30, is another type of final transmission that has met with a considerable amount of success, particularly on the Leyland machines of five-ton and six-ton capacity. The differential gear and the bevel-drive reducing gear are both enclosed within a casing that is bolted to a fixed back axle; the ends of the driving shaft pass through tunnels in the axle body; and claw pieces on the outer ends of the differential shaft engage with similar claws on the road-wheel hubs. The two last-named forms of gear are highly efficient, provided the pitch and shape of the teeth are carefully considered and the designs provide for the encasing of all the pinions and gear rings.

The only other type of final drive which is used to any great extent for commercial motors is that which employs a hardened and ground steel worm meshing with a machine-cut phosphor-bronze worm wheel which is bolted to the differential-gear cage of a live back axle. The employment of this type of gear for the final transmission on commercial motors generally leads to increased efficiency, on account of the ease with which all the parts can be enclosed in an oil-tight casing. It also gives silence of running. The strongest advocate of the worm drive for heavy vehicles is the Guildford manufacturer, Dennis Bros., Ltd., one of which company's machines is illustrated in fig. 31. Although there are many difficulties in the matter of the manufacture of worm gearing, they are not insurmountable, and, given proper attention at the hands of the designer, followed by accurate workmanship, probably no other mechanical means of transmitting power can approach it for smooth and silent operation. Both thrust bearings on the worm shaft should be on one side of the worm, to avoid lack of truth in meshing if any heating occurs between the worm and the wheel. There are many examples of the worm drive to be found in London on public-service passenger vehicles, and also on delivery vans. One of the great charms of this type of transmission is that a very large gear reduction may be obtained without making the worm wheel unduly large in diameter; this is an important factor in the design of a back axle, as every inch of road clearance is of value for operating on rough country roads. As a large gear reduction is thus rendered possible on the back axle, it will readily be understood that the change-speed gear-box may be made considerably smaller than would be necessary for a bevel-driven live axle, where a large gear reduction is not permissible, both on account of its size and because such a gear would be very noisy in its working.

Although the use of tooth wheels is still the only practical method of obtaining variable transmission for motor vehicles, the fundamental defects of transmission in this way are inherent to the system and must always be present; they are now less apparent, thanks to the remarkable improvement which has taken place in the use of suitable materials and improved design.
It is still the hope of some manufacturers that a form of infinitely variable change-speed device will be produced, which will replace the step-by-step movement of toothed gearing; the two chief directions in which this has been attempted are electrical and hydraulic. Of these two, electrical devices are really step by step, and the hydraulic method is apparently the only one that permits of infinite variation. Enormous sums of money have been spent in the search for an effective hydraulic

Fig. 33.—70 h.p. Six-cylinder Dennis Fire-engine with Gwynne Centrifugal Pump.

back road wheels, through a worm and worm wheel. The changes of vehicle speed are effected by altering the method of grouping the electrical windings of the dynamo and motor field-magnets and armatures. This system of control is known as the series-parallel, and is effected by a single lever, which actuates a mechanical switch, or "controller."

In one of the most-recently-introduced petrol-electric systems—the "K.P.L." system, as worked by the Daimler Co., of Coventry—each of the rear road wheels is provided with a separate power unit, consisting of a four-cylinder petrol engine, which is direct coupled to a dynamo, the armature of the latter being coupled to a worm which meshes with a worm wheel attached to the road wheel. A small electrical storage battery forms part of the system, and this receives the excess of current from the dynamotors when the whole power of the engine is not required for the propulsion of the vehicle. When the machine is being driven up a steep incline, or when it is required to travel in a reverse direction, the battery may be called upon to supply current to the dynamo, and, in this manner, the power of the engine is augmented by the dynamotors' working as electric motors.
MOTRIL—MOTT, V.

Still another petrol-electric system is that invented by Mr. Thomas. In this system, which is at the same time the simplest and most practical form of petrol-electric transmission, two dynamos and an epicyclic gear are employed so that the electrical load is at no time greater than one half of the total load; consequently, the risk of a "burn out" of the windings, as the result of sudden and unforeseen periods of overload, is materially minimized.

Special Applications.—Amongst the special applications of the petrol-engined commercial vehicle is the motor fire-engine, which has brought to the front in this branch several enterprising motor manufacturers, amongst whom Dennis Bros., of Guildford, Halley, of Glasgow, and Leyland, of Preston, are prominent. The general construction of the chassis closely follows the lines of other petrol vehicles of equal load capacity, but the gear-box tail-shaft is prolonged to the after-end of the machine, and is direct-coupled to the rotary member of a multi-stage centrifugal pump. In the Dennis fire-engine, the vacuum which is necessary in order to lift the water in the suction hose is obtained by means of priming the pump chamber, further assisted by a water ejector and a small water tank which is carried on the machine. This machine is shown in fig. 35, while fig. 36 shows the successful motor fire-engine built by Halley's Industrial Motors, Ltd., of Yoker, Glasgow. In the latter machine, as also in the Leyland and other fire-engines which employ centrifugal pumps, the vacuum is created by means of reciprocating air pumps. These machines have given very satisfactory results in the hands of practical firemen, in various parts of the United Kingdom and abroad. Merryweather and Shand-Mason, who were formerly builders of steam fire-engines, now also build petrol-engined machines, these makers favouring reciprocating water pumps.

Other special applications of the internal-combustion motor are for grass mowing and rolling, and for road mending and rolling gravel paths, &c. One of the latter type of machines is shown in fig. 35. In this machine a petrol or paraffin engine drives a water-ballast roller through the medium of a clutch, a simple form of change-speed gear-box, and a single roller chain. The leading roller, by which steering is effected, is also filled with water, in order to obtain the dead weight necessary for rolling. Marshall, Sons & Co., Ltd., of Gainsborough, Thornycroft, of Basingstoke, and Broom & Wade, of High Wycombe, have also produced special machines for agricultural and military purposes, and one of the smallest tractors built by the first-named maker is shown in fig. 36. The engine is one of the two-cylinder type, consuming paraffin fuel, and driving the live back axle through a substantial gear-box and a final drive of the externally-toothed type. Such a machine is well below the weight limit for heavy motor-cars. Fig. 37 shows a more powerful oil tractor by Thornycroft. This machine is the same type which was so successful in the tractor trials promoted by the British War Department in March 1909. It is capable of hauling a gross load of seven tons practically anywhere, and even of lifting that load vertically by means of its winding cable. The engine has four cylinders, and the fuel may be paraffin, alcohol or crude oil.

MOTRIL, a town of southern Spain in the province of Granada, at the foot of an offshoot of the Sierra Nevada and on the edge of a rich alluvial plain, about 1 m. from the Mediterranean and 40 m. S.S.E. of Granada, with which it is connected by a good carriage road. Pop. (1900), 18,528. The climate is semi-tropical, and the segra or plain of Motril has been found peculiarly adapted for the culture of sugar-cane and sugar-beet. In the district, and especially at Salobreña, 3 m. west, there are numerous sugarfactories; cotton is also grown and manufactured, and alcohol, flour, soap, iron goods and cotton stuffs are among the other industrial products. The neighbourhood is rich in zinc and lead; and copper is also found. Motril itself is a port of the second class, but the anchorage at Calahonda, 45 m. south-east, is much better. Grapes, barley, esparto grass, dry figs, almonds and zinc are exported.

MOTT, LUCREIA (COFFIN) (1793–1880), American reformer, was born at Nantucket, Massachusetts, on the 3rd of January 1793. She was descended on her mother's side from Peter Polk, founder of the first firm of Nantucket, and the grand-father of Benjamin Franklin; her father's ancestors were among the first settlers of Nantucket. At thirteen she was sent to a Friends' boarding school, at Nine Partners, near Poughkeepsie, New York, where James Mott (1788–1868), who like her was of old Quaker stock and whom she married in 1811, was then a teacher. In 1810 James Mott entered the employ of Lucretia's father in Philadelphia, but the business was not successful and in 1817 Lucretia opened a small school under the care of the Pine Street Monthly Meeting, but gave it up a year afterwards and in the same year was recognized by the Friends as an "acknowledged minister." Her husband had as early as 1822 espoused the cause of Elias Hicks against the "Orthodox" Friends, and in 1827, when the Society divided, Lucretia joined the Hicksites. Hicks's teachings on slavery had impressed both James and Lucretia; in 1830 James gave up a lucrative cotton commission business that he might not profit from the products of slave labour; and both took an active part in the campaign against slavery. About 1840 Mrs. Mott also took up the cause of woman's rights. On lecturing tours she and her husband travelled as far as Indiana and into Maryland and Virginia. In 1848 she addressed the Anti-Sabbath Convention in Boston, and with Elizabeth Cady Stanton, whom she had first met in London in 1849, called a convention "to discuss the social, civil and religious condition and rights of women," which met at Seneca Falls and passed a "Declaration of Sentiments," modelled on the Declaration of Independence. Her husband, who was prominent among the founders of Swarthmore College (1864), died in Brooklyn, New York, on the 26th of January 1868; and Mrs Mott died on the 11th of November 1880 near Philadelphia.

See James and Lucretia Mott: Life and Letters (Boston, 1884), edited by their granddaughter, Mrs Anna Davis Hallowell.

MOTT, VALENTINE (1785–1856), American surgeon, was born at Glen Cove, New York, on the 20th of August 1785. He graduated at Columbia College, studied under Sir Astley Cooper in London, and also spent a winter in Edinburgh. After serving as demonstrator of anatomy he was appointed professor of surgery in Columbia College in 1809. From 1811 to 1814 he was in very extensive practice as a surgeon, and most successful as a teacher and operator. He tied the innominate artery in 1818; the patient lived twenty-six days. He performed a similar operation on the carotid forty-six times with good results; and in 1827 he was also successful in the case of the common iliac. He is said to have performed one thousand amputations and one hundred and sixty-five lithotomies. After spending seven years in Europe (1834–1841) Mott returned to New York and founded the university medical college of that city. He translated A. A. L. M. Velpeau's Operative Surgery, and was foreign associate of the Imperial Academy of Medicine of Paris. He died on the 26th of April 1865.
MOTTEUX, PIERRE ANTOINE (1663–1718), English translator and dramatist, of French parentage, was born at Rouen on the 25th of February 1663. After the revocation of the Edict of Nantes he settled in London with his kinsman and godfather, Paul Dominique Motteux. He acted as an auctioneer of pictures, and in 1706 he had a shop in Leadenhall Street for the sale of lace, stuffs, Chinese and Japanese commodities, duly advertised in the Spectator by his friend Richard Steele. He had not been six years in England when he obtained sufficient mastery of the language to edit the monthly The Gentleman's Journal, which contained verses by himself and by the chief wits of the day. In 1693 he edited the third book, hitherto unpublished, of Sir Thomas Urquhart's translation of Rabelais, and in the next year printed the first and second books of Urquhart's translation. In 1694 he completed Urquhart's work by a translation of the fourth and fifth books, which, although not to be compared with the racy, nervous writing of Urquhart, shows a perfect mastery of colloquial English and an intimate and adequate sense of Rabelais's meaning. The complete translation appeared in five volumes in 1693–1694, and was reprinted as The Whole Works of Franci Rabelais, M.D. (2 vols., 1708), described as the work of “Sir T. Urchard, Knight, Mr Motteux and others.” His first play, a comedy in five acts entitled Love's Jest, was produced at Lincoln's Inn Fields in 1696, and next year followed The Loves of Mars and Venus. He wrote other works for the stage of no great consequence. More important than his dramatic work is his History of the Renowned Don Quixote de la Mancha (4 vols., 1701; 2nd ed., 1712), “translated from the original by many hands and published by Peter Motteux,” one of the most masterly and spirited translations in English. His later years appear to have been spent in the shop in Leadenhall Street. He was murdered on the 18th of February 1718 at a house of ill fame in Star Court, near St. Clement's Church, London, under circumstances which have never been cleared up. The manner of his death was no criterion of his life, which appears to have been sober and decent.

An excellent life by Henri van Laun is prefixed to the 1880 reprint (4 vols.) of J. G. Lockhart's edition of Motteux's Don Quixote. See also a prefatory note by Charles Whibley in vol. iii. of Sir T. Urquhart's Rabelais (Tudor Translations, 1900), reprinted from a rare 1693–1694 edition.

MOTTEVILLE, FRANÇOISE BERTAULT DE (c. 1621–1669), French memoir writer, was the daughter of Pierre Bertaun, a gentleman of the king's chamber, and niece of the bishop-poet Jean Bertaun. Her mother, a Spanishwoman, was the private secretary of Anne of Austria, wife of Louis XIII. At the age of seven Françoise was also made a member of the queen's household and given a pension. The influence of Richelieu, however, who wished to separate the queen from her Spanish connexions, exiled mother and daughter to Normandy, where in 1639 the young girl was married to Nicolas Langlois, seigneur de Motteville, president of the Chambre des Comptes of Rouen. He died two years later at the age of eighty-two, and in 1642 the queen summoned Mme de Motteville to court, being now her own mistress by the death of Richelieu and Louis XIII. Through all the intrigues and troubles of the Fronde Mme de Motteville preserved the honourable reputation of being devoted to her mistress without any party ties or interests. Some letters of hers are preserved—especially a curious correspondence with La Grande Mademoiselle on marriage, but her chief work is a study which is in effect a history of Anne of Austria, written briefly till the date of Mme de Motteville's return to court, and then with fullness. They give a faithful picture of the life of the court at that time.

The best edition of her Mémoires is that of M. F. Riaux (2nd ed., Paris, 1891, 4 vols.), containing the essay by Sainte-Beuve from vol. v. of his Causseries du lundi. The Mémoires were translated into English by the Rev. J.O. L. tutors of the English in Rouen. For details concerning her family see Recherches sur Madame de Motteville et sur sa famille, by Charles de Beaurepaire (Rouen, 1900).

MOTTI, FELIX (1856– ), German conductor and composer, was born near Vienna, and had a successful career at the Vienna Conservatoire. He became known as a gifted conductor of Wagner's music, and in 1876 was engaged for the Ring des Nibelungen at Bayreuth. From 1881 to 1903 he was conductor at the Carlsruhe Opera, and made a wide reputation for his activity there, particularly in producing the works of Wagner and Berlioz. In 1886 he directed the performance of Tristan und Isolde at Bayreuth. In later years he visited London and New York, and became known as one of the most brilliant conductors of his day; and in 1904 he was made a director of the Academy of Music at Berlin. He composed some operas, of which Agnes Bernauer (Weimar, 1886) was the most successful, and numerous songs and other music.

MOTTO (an Italian word, from Late Lat. mutum, a low sound, a mutter or murmur, cf. mutere, to mutter; the Latin word also gives Fr. mot, word), a "legend" consisting of a significant phrase or sentence, sometimes even of a single word attached to an emblem or device, and, in heraldry, placed on a scroll below the achievement or above the crest. Mottoes express sometimes a sentiment, a favourite principle, emphasize the meaning or symbolism of the emblem or device, and, in heraldry, often allude to one or more of the "charges" in the coat of arms, &c.

There are many publications which give lists of some of the best-known mottoes, such as Fairbairn, Book of Family Crests, 1856; Wachbourne, Book of Family Crests (3 vols., 1882); Chassant and Langlois, Dictionnaire des armes, des blasons et des alliances, 4 vols. (1878); Diel, Die Welt- und Denkenspruch; Feldgeschichte, Literaturgeschichte, Schicksal und Volksrufe, besonders des Mittelalters und der Neuzeit (4 vols., 1888). Gathfield's Guide to Printed Books and M.S.S. relating to Heraldry (1892) contains a bibliography.

MOTTA, an ancient Phoenician settlement in Sicily, on a low island [mod. S. Pantaleo], 5 m. north of Lilibaeum [mod. Marsala]. It was the centre of the Phoenician trade in Sicily. It was accessible from the mainland by a mole, which is still used as a track for wagons. The line of the city wall, of rough rectangular blocks of stone without mortar, may still be traced. A round the coast with two gates, one on the north towards the mole, which is still in part preserved, and one on the south. The date of its foundation is uncertain. In 398 B.C. it was taken after a desperate struggle (which, owing to the height and strength of the houses, continued even after a breach had been made in the city wall) by Dionysius of Syracuse, but recovered in the next year: it was, however, abandoned by the Carthaginians, and its place taken by Lilibaeum on the mainland.

MOUCHEZ, AMÉDÉE ERNEST BARTHÉLÉMY (1821–1892), French astronomer, was born at Madrid of French parents on the 24th of August 1821. At the age of sixteen he entered the naval school at Brest, and after serving with distinction in various ships, was appointed in 1856 to the command of the “Bison.” Towards the close of the Franco-Prussian War he made an admirable defence of Brest, and his organization of the French expedition to the island of St Paul to observe the transit of Venus in 1874 obtained his election to the Academy of Sciences and his promotion as commander of the Legion of Honour. On the 27th of June 1878 he succeeded Urbain Leverrier as director of the National Observatory of Paris, and was raised to the rank of rear-admiral. The fourteen years of his directorship were marked by a great increase in the activity of the institution. The observatory grounds were enlarged; two powerful instruments of the novel kind known as coudé equatorial instruments were installed; a spectroscopic department was established, and the gigantic task of re-observing all Lalande's stars was completed. He published twenty-one volumes of Annales, as well as the first two volumes of the great Catalogue de l'observatoire de Paris; founded the Bulletin astronomique, and set on foot two schools of practical astronomy, one at Paris, the other at Montsouris, for the special instruction of naval and military officers, explorers and surveyors. His most memorable work, however, was the inauguration of international operations for charting the heavens. The advances in stellar photography made by Paul and Prosper Henry and others suggested to him the magnificent idea of obtaining, through the collaboration of astronomers in all parts of the world, an
autographic picture of the entire sphere containing more than fifty million stars, which should faithfully record in future ages the state of the sky at the end of the 19th century. Although he did not live to see its completion, he had the satisfaction of knowing that the ultimate success of this vast scheme was assured. He died suddenly at his country seat at Wissous, near Antony, on the 25th of June 1892.

MOUFLON, or Muflon, the wild sheep (Ovis musimon) of Corsica and Sardinia, where it is now very local. The ewes are either hornless or provided with quite small horns, the hornless form being probably characteristic of one island and the horned of the other. The rams carry good horns, and in summer show a conspicuous light saddle-shaped mark on the otherwise dark-coloured coat. The Armenian mouflon (O. orientalis), of Persia, Armenia, and the Tróodos range of Cyprus, is typically a larger and redder sheep, with the horns curving in the reverse direction; but the Cyprian race is small. (See SHEEP.)

MOULD, (1) (O. Eng. molde, from a Teutonic root meaning to grind, reduce to powder, cf. “meal”), loose fine earth, rich in organic matter, on the surface of cultivated ground, especially the made garden soil suitable for the growth of plants. In the sense of a furry growth, consisting of minute fungi found on animal or vegetable substances exposed to damp, the word may be either an extension of “mould,” earth, or an adaptation of an early “moull,” with an additional d due to “mould.” “Moul” is a Scandinavian word, cf. Swed. mölga, to grow musty, and the Eng. colloquial “muggy.” (2) A form or pattern, particularly one by means of which plastic materials may be made into shapes, whence “moulding,” the form which the material so shaped takes. The word comes through the O. Fr. molle, molé, from Lat. modulatns, a measure, or standard. The English “model” is another derivative of the same word.

MOULDINGS, the term in architecture for the decorative treatment given to projecting or receding features in stone, wood and other materials, by means of curved forms, whereby those features are accentuated and varied owing to the play of light and shade on the surfaces. The principal characteristics of all the European styles are to be found in the mouldings employed in them and in their ornamental decoration. In some of the earlier styles, such as the Assyrian and the Persian, there are no mouldings: coloured bands in brick, enamelled tiles or beton, were deemed sufficient to mark the divisions of their storeys or to decorate their buildings. The Egyptians employed two mouldings only, the cavetto (fig. 1), a deep moulding sometimes of great dimensions which crowned their pylons, temples and decorative shrines, and the torus, a semicircular projecting moulding which was carried above the architrave and down the quoin of their buildings. The Greeks were the first to recognize, in their temples, the special value possessed by mouldings, which, occupying an intermediate position between

the ornamental sculptures and the simple architectural lines of the main structure, gave a richly decorative effect to the latter without interference with the beauty of the former.

The Classic mouldings may be divided into two classes, simple and compound; to the former belong the cavetto (of small dimensions when compared with the Egyptian cavetto) and the Scotia (fig. 2), employed for the bases of columns, which are seen below the eye, both concave mouldings, whilst the ovo or echinus—Fr. ovo or quart de rond—(figs. 3 and 4) and the torus are convex mouldings. The compound mouldings are those composed of curves of contrary flexure, such as the cyma recta or cymatium (fig. 5), of which the upper part is concave and the lower convex, a moulding constantly employed for the upper member of the cornice, and the cyma-reversa or ogee (fig. 6)—Fr. talon—in which the upper portion is convex.

The Greeks sometimes varied the ogee moulding, the upper portion of which is turned back and the lower portion brought forward, and to this the term quirked ogee (fig. 7) is given. Another Greek moulding of compound form is the bird’s beak (fig. 8), employed as a drip moulding above the corona. Of smaller dimensions is the astragal (fig. 9), a moulding invariably carved with the bead and reel, which in Greek work is constantly used in conjunction with the enriched echinus and cyma-reversa mouldings (figs. 18, 20) and below the necking of Ionic capitals: and the listel or fillet, employed chiefly in the separation of curved mouldings one from the other; in the cymatium constituting its upper termination (fig. 5), and in the Scotia (fig. 2) its upper and lower border. In Classic work generally the cavetto is only employed for the apophyge under the capital and over the base, but in Roman work, as in the theatre of Marcellus, it sometimes took the place of the cymatium of the cornice. Although extremely simple in its form, the finest Greek moulding, and the one to which the Greeks apparently attached the greatest value, was the echinus under the abacus of the Doric capital. The earliest archaic example exists in the capital of the shafts flanking the tomb of Agamenon at Mycenae (4, fig. 10), where it consisted of a large torus decorated

with the chevron (see CAPITALS), and an apophyge carved with the petals of a flower; a similar decoration of the apophyge is found in two or three early Doric capitals, as at Paestum and Metapontum, but this is the only example known in which the echinus of the Doric capital was carved, though traces of painting and gilding have been found on them. Other examples showing the gradual development of the echinus are shown in fig. 10; b being from the temple at Corinth, c from the Parthenon at Athens, d from the portico at Delos, e an early Roman example (c. 60 B.C.) of the temple at Cori, and f from the theatre of Marcellus, where it nearly approaches the quarter round always employed in late Roman work and in the Renaissance.

There is one other important decorative feature which forms the most characteristic feature of the bedmould of the Ionic cornice, viz. the dentil cornice (fig. 11), derived originally from the ends of the squared timbers which carried the cornice of the primitive Ionic temple, and in the earlier stone examples copied more or less literally; it subsequently in the 4th century was introduced as a part of the bedmould of the cornice of the Ionic Order, the temple of Minerva Polias at Priene in Asia Minor being one of the best examples. It consists of a series of projecting blocks with intervals between them equal to half
the width of the block. In the Greek Corinthian Order it was first introduced into the Choragic monument of Lysicrates. It was constantly employed by the Romans in their temples of the Ionic and Corinthian Orders, the finest example being in the bedmould of the temple of Castor in Rome, where it is twice the height of the other mouldings.

In the Romanesque style the mouldings consist almost entirely of rounds and hollows, the former known as the bowtel,

and in England, France, Spain and Germany employed to decorate or soften the angle of an arch mould. As the Romanesque arch frequently consisted of two or more rings of arches, projecting one in front of the other, to which rings the term “order” is sometimes given, the repetition of this simple moulding constituted an ample decoration by itself, but in the Norman work in England and the north of France there is found the constant recurrence of mouldings broken into zigzag lines and other decorations coming under the head of ornamental mouldings described below. The simple bowtel (fig. 12) was retained in France far into the Gothic period, but in the Early English style the mouldings (fig. 13) became lighter, being more boldly cut than in the Romanesque styles. Here again, as in the earlier style, each ring or order is enriched with a succession of alternate rounds and hollows, the latter being very deeply cut, and a few small fillets. The bowtel also is brought out to an angle which is sometimes emphasized by a small fillet; this is sometimes called the keel moulding from its resemblance in section to the bottom of a ship. Sometimes the angle of the ring is splayed, and the mouldings are worked on the splay, and this is very often found in the mouldings of the ribs of a vault (fig. 13a), giving greater lightness to the rib. The mouldings of the Decorated period (fig. 14) are more diversified than those of the Early English, and the hollows towards the end of the period become shallower and broader, oges being frequently employed. One of the chief characteristics of the Perpendicular period (fig. 15) is the prevalence of large shallow hollows and the employment of two oges in close contact with the convex sides next each other.

The French mouldings of the Gothic period in Normandy and adjacent parts follow very much on the same lines as those in England, but in the south of France and in Germany they are very much simpler, and one rarely finds the deep hollow which forms the chief characteristic of English mouldings. In French flamboyant and late German Gothic work the mouldings run through, penetrating one another; these in Germany were sometimes cut off, having the appearance of the smaller stems of a tree from which some of the boughs have been lopped.

Ornamental Mouldings.—Although the mouldings in Greek and Roman architectural works are in general form much the same, they vary materially in their profiles and also in the refinement of their enrichment with carving. It is probable that the earliest decoration of mouldings was confined to the painting only of their surfaces, and in one or two of the more archaic examples traces of painting only are found on them. The desire to accentuate the ornament would seem to have led the Greeks at a very early date to incise or raise in relief the decorative designs which originally were painted only; at first this was done very sparingly, and in the earlier buildings but few mouldings were employed; in course of time they increased in number, and in the Augustan period in Rome the carving extended to the flat surfaces of the corona, and the fascia and soffits of the architrave.

The four principal Classic mouldings, so far as their enrichment with carving is concerned, were the cyma-recta or cymatium; the cyma-reversa or ogee; the echinus or ovolo; and the torus. The cymatium was almost always decorated with a conventional treatment of the flower of the acanthus plant, known generally as the anthemion and sometimes as the honeysuckle; the finest example is that which is found in the cornice of the north doorway of the Erechtheum (fig. 16). Although in some cases the flower of the acanthus is repeated in the Roman cymatium, the rigidity of the other lines does not seem to have appealed to the Roman sculptor, who preferred more foliage, such as is shown in the cymatium of the Forum of Nerva (fig. 17), there being endless variety of design in Roman examples. The ogive-moulding in Greek work was always carved (fig. 18) with the Lesbian leaf (Fr. rais-de-cœur; Ger. Herzblatt), which in Roman work received a peculiar interpretation of the original design; not understanding the

modelling of the leaf and requiring a deeper shadow, the Roman drilled holes in it and evolved another composition of two leaves, so that the outer edge of the Lesbian leaf formed a trefoil cusp (Fr. talon trifle), constituting a new description of border, as shown in fig. 19, from the temple of Castor at Rome. The ovolo moulding, whether employed in the bedmould of a cornice, on the capital of an anta, or in the Ionic capital, was always carved (fig. 20) with the egg and dart enrichment (Fr. ovo et dard; Ger. Eierstab), which was spread out wider by the

Roman carver, while holes pierced on each side of the tongue changed its design into that of the egg and tongue (fig. 21). In both the enriched ogee and the carved ovolo the design was never complete without the bead and reel underneath (figs. 20 and 21), there being always two beads and four reels to each leaf of egg. When employed as the crowning moulding of an architrave, the ogee is always capped by a fillet; and the same applies to the cymatium of the cornice. When the ogee moulding was of small size and employed in a subordinate position, as is constantly done in Roman work, crowning the modillion
or subdividing the fascia of the architrave, a simpler leaf pattern was employed.

Though not a moulding, the modillion, which was invented by the Romans to give additional support to the corona, forms part of the bed mould of the cornice, and may therefore be described here. It consists of a small bracket (fig. 22), the design of which was probably derived from the vertical console bracket which carried the cornice of the Greek doorways, but which in the Roman cornice was employed horizontally. The design of the outer side is that of an Ionic volute with its cushion; on the inner side the volute is reversed and is of greater size, the soffit being masked by a leaf.

The torus moulding of the base in early examples was fluted but not carved, and the earliest example so treated is that found in the base of the columns of the Erechtheum, where it was enriched with the triple guilloche. In the temple of Apollo Branchidae, near Miletus in Asia Minor, where they would seem to have attempted to rival the figure decoration of the temple of Diana at Ephesus, the torus mouldings were elaborately carved with the acanthus plant and the laurel leaf; but it was in the Augustan age in Rome that the greatest elaboration was given to the torus of the base; in the Ara Pacis, set up in A.D. 13, it was carved with the double guilloche; the finest Roman example of an enriched torus being that of the base of the Trajan column in Rome, which is carved with laurel leaves tied at intervals with bands.

The principal enriched Byzantine moulding is that known as the Venetian dentil (fig. 23), in consequence of its constant employment in Venice and the towns in its vicinity. Its earliest appearance, however, is in Sta Sophia at Constantinople (A.D. 537). The other carved Byzantine mouldings are those which throughout Syria form richly carved string-courses, taking the place of the Classic cornice, and the hood moulds of arches. The Byzantine string-course, which is found in St Mark's, Venice, and in most of the towns bordering on the Adriatic, is a cyma-recta carved with the acanthus leaf.

The enrichments of the mouldings of the Romanesque style are of great variety; in parts of Italy and in the south of France they were largely influenced by Byzantine work; but in Sicily, Apulia, Normandy and England the Normans introduced a series of purely geometrical forms in which the chief peculiarity is the rare occurrence of foliage. The most characteristic example is that of the zigzag or chevron (figs. 24, 25), of which the ball flower (fig. 30) follow, these being all carved in the hollow of cavetto mouldings. In the Decorated and Perpendicular styles, the flowers and foliage introduced in mouldings become more natural, till one reaches the Tudor rose (fig. 31), a precise copy of the flower, beyond which it was difficult to go.

In the 16th century the enrichment of mouldings passed through a transitional stage, being half Gothic and half Classic, and on the introduction of the purer Italian style Roman profiles and decoration were again employed. The Greek revival at the commencement, and the Gothic revival in the middle, of the 19th century naturally brought about a reaction in favour of purer Classic forms or of Gothic work, but the vernacular types could not be displaced by the passing fashion, and the influence of Robert Adam is again paramount to-day.

Moulin (Fr. moulin, a mill), in physical geography, the name given to the swirling cascades which are formed by glacier streams pouring into crevasses, and result in the formation of giant's kettles.

Moulin Quignon, a quarry near Abbeville, France, celebrated for the discovery in 1863 by Boucher de Perthes of a human jaw-bone believed to be referable to the Quaternary period. By his collection of flints Boucher de Perthes had been the first to attempt to establish the existence of man in remote ages; but it had been objected that if the flints were indeed the work of man, human remains would have been found in association with them. Considerable excitement therefore was created both in England and France by the "find" of bones at Moulin Quignon, and a commission of inquiry was appointed. The report was favourable to the genuineness of the relics, but latterly doubts have arisen as to whether they can be regarded as earlier than the Neolithic age.

Mouins, a town of central France, capital of the department of Allier, 127 m. by rail N.W. of Lyons. Pop. (1906), 18,997. The town is situated on the right bank of the Allier, which is here crossed by a remarkable bridge of the 18th century about 1000 ft. in length. Mouins did not attain any importance till the 14th century, before which it consisted chiefly of some mills belonging to the dukes of Bourbon. The medieval town occupied a small area, the boundaries of which are marked on the N.E. and S. by the central boulevards occupying the site of the old moats. The modern town, expanding from this nucleus, is limited on the east and south by the railway, the southern portion being traversed by agreeable promenades. To the north is the spacious avenue known as the Cours de Bercy, close by the hospital and the lycée. The more interesting buildings lie within the old enceinte. The chief of these is the cathedral, which consists of a huge choir of the 15th and 16th centuries, and a nave in the early Gothic style but modern in construction and terminated by two towers with stone spires rising to a height of 312 ft. The church possesses a fine triptych attributed to Domenico Ghirlandajo (d. 1494), and fine windows of the 15th and 16th centuries. Among the oldest buildings in the town are the square tower of the 14th century (used as a prison) which is the chief relic of the château of the dukes of Bourbon, and a belfry of the 15th century. Part of an old Jesuit college serves as the court-house, which contains an archaeological museum. The library, which possesses a valuable Bible of 1115, is part of the hôtel-de-ville. Numerous mansions of the 15th and 16th centuries border the streets of the
old quarter of the town. There is a statue of the poet Théodore de Banville, born at Moulins in 1823. The town is the seat of a prefecture, a bishopric, and a court of assizes, and has tribunals of instance and commerce, and a branch of the Bank of France. Yzeure, 1½ m. E. of Moulins, has an interesting Romanesque church (12th century); ¾ m. W.S.W. of Moulins is Souvigny, formerly famous for its Cluniac priory. Its church, a fine building of the 11th and 12th centuries, restored in the 15th century, contains the splendid tombs of Louis II. and Charles I., dukes of Bourbon in the 15th century, and other tombs of the Bourbon family, now in ruins.

Moulins became the residence of the dukes of Bourbon about the middle of the 14th century, and capital of the duchy towards the end of the 15th century. In 1566, under Charles IX., an important assembly of notables was held in the town, at which the judicial system of France was reorganized.

MOULTON, or Moulins, the port and headquarters of Amherst district and Tenasserim division of Lower Burma. The population in 1901 was 53,456, and the increase in the last quarter of a century has been very slight. Ship-building, which formerly was an important industry, has now been given up, but there is still a considerable export of teak and rice, and there are several steam rice- and saw-mills. The total exports average more than a million sterling. Three steamers run weekly to Rangoon. Germany and Siam are represented by consuls; Persia, Denmark, and Norway and Sweden by vice-consuls; and Italy and the United States of America by consular agents. The garrison of Madras native infantry, formerly stationed in the town, was withdrawn in 1898. The town, which has the appearance of being on a river, the Luille, and lastly on the sea, with the island of Bilugun in front. It is one of the most picturesque ports in the East. There is a branch of the Bank of Bengal, and two newspapers are published—one in English and one in Burmese.

MOULT, a term for the shedding of feathers at the periodic renewal of the plumage by birds, and so transferred to the periodic shedding of the old skin, shell, &c., by other animals. The word is seen in O. Eng. in the verb bimaulian, to exchange; from Lat. mutare, to change; cf. mod. Ger. mausen, mausern; the earlier forms in English are moui, mute, the insertion of the / from “fault,” dates from the 16th century.

MOULTON, LOUISE CHANDLER (1833–1908), American poet, story-writer and critic, daughter of Lucius L. Chandler, was born in Pomfret, Connecticut, in 1833. In 1855 she married a Boston publisher, William U. Moulton (d. 1868), under whose auspices her earliest literary work had appeared in The True Flag. Her first volume of collected verse and prose, This, That and the Other (1854), was followed by a story, Juno Clifford (1855), and by My Third Book (1859); her literary output was then interrupted until 1873 when she resumed activity with Bed-time Stories, the first of a series of volumes, including Firelight Stories (1883) and Stories told at Twilight (1890). Meanwhile she had taken an important place in American literary society, writing regular critiques for the New York Tribune from 1870 to 1876 and a weekly literary letter for the Sunday issue of the Boston Herald from 1886 to 1891. In 1876 she published a volume of notable Poems (revised Swallow-Nights in the English edition of 1877) and visited Europe, U. Midwest in 1876, which she called the largest of the world. Thenceforward she spent the summers in London and the rest of the year in Boston, where her salon was one of the principal resorts of literary talent. In 1886 another volume of verse, In the Garden of Dreams, confirmed her reputation as a poet. She also wrote several volumes of prose fiction, including Miss Eyre from Boston and Other Stories, and some descriptions of travel, including Lazy Tours in Spain (1866). She was well known for the extent of her literary influence, the result of a sympathetic personality combined with fine critical taste. She died in Boston on the 10th of August 1908.

See Liquid Whiting, Louise Chandler Moulton (Boston, 1910).

MOLYNEUX, JOHN (1700–1874), English poet, was born in London on the 30th of December 1799. He was educated at Eton, and many of his best verses were contributed to the Eltonian. He entered Trinity College, Cambridge, in 1810, and in 1812 began to reside at the Middle Temple. Three years later he was ordained, and was presented to the living of Rugby by Lord Craven. At Rugby he became intimate with Thomas Arnold, to whom two of his best sonnets are addressed. He died at Rugby on the 26th of December 1874. He published several volumes of verse during his lifetime, and a complete edition of his poems was published (2 vols., 1876) with a memoir by Derwent Coleridge. They include, amongst much that is dull, some popular pieces, “Godiva,” “Three Minstrels,” an account of meetings with Wordsworth, Coleridge and Tennyson, “My Brother’s Grave,” and some excellent hymns.

MOULTON, THOMAS (1730–1805), American soldier, was born in Charleston, South Carolina, on the 23rd of November 1730. His father, a physician, and a graduate of the University of Edinburgh, migrated to Charleston before 1729. The son was elected to the Commons House of the Assembly in 1754, 1769 and 1772; and in 1760 he was captain of a provincial regiment in the expedition under Governor William H. Lyttelton against the Cherokees. Although he was connected by many ties to the British, he espoused the American cause on the outbreak of the War of Independence, and was a member of the first provincial congress (1775) of South Carolina, which in June made him a colonel of the Second South Carolina regiment; and he was a member of the second provincial congress (1775–1776). On Fort Johnson, on James Island in Charleston harbour, he raised what is said to have been the first American battle-flag—blue, with a white crescent in the dexter corner, inscribed with the word “Liberty” the flag was devised by him in September 1775. In March 1776 he took command of a palmetto fort which he had built on Sullivan’s Island, off Charleston, which he held against the attack of Admiral Sir Peter Parker on the 28th of June, and which soon after the battle was renamed Fort Moultrie by the General Assembly. He was thanked by Congress, was made a brigadier-general in the continental army in September 1776, and was placed in command of the department of Georgia and South Carolina. He dissolved the British from Beaufort, South Carolina, in February 1779, and in April made it possible for the city of Charleston to put itself into a state of defence by delaying the advance of General Augustine Prevost. He was one of those who advised against the surrender of Charleston, which he held until he was replaced by General Benjamin Lincoln. His imprisonment after the surrender of Charleston (May 1780) lasted until his exchange with others for General Burgoyne in February 1782. In October 1782 he was made a major-general. He was governor of South Carolina in 1785–1789 and in 1792–1794. He died in Charleston on the 22nd of September 1805.

He wrote Memoirs of the Revolution so far as it Related to the States of North and South Carolina (2 vols., 1802).

MOUND, now used in the sense of a pile or heap of earth, artificial or natural, especially such a pile raised over a grave or burial-place, a tumulus, or as a means of defence, and so used to translate Lat. ager. The earliest use in English is for a hedge or other boundary between adjoining lands; this only is admissible of the word “mound” in origin, but was early influenced by “mount,” i.e. hill; Lat. mons, montis. A connexion with O. Eng. mound, guardianship, hand, has been suggested. The “orb,” i.e. a globe of gold surmounted by a cross, as forming part of the regalia (q.v.), is often known as a “mound”; this is a translation of Fr. mout; Lat. mundus, world.

MOUND-BUILDERS, in North America, the name given to the prehistoric inhabitants who chiefly centred in the valleys of the Mississippi and Ohio, and who seem to have possessed a measure of civilization far in excess of that of the North American Indians when first met by the whites. The remarkable mounds, which have given occasion for the name, are fortified enclosures and tumuli of the most varied appearance, round, conical, or in the shape of animals. They are scattered...
over an immense tract of country from the great lakes to the Gulf of Mexico, and from the Rockies to the Atlantic, but are specially frequent in the valley of the Mississippi, along its left tributaries, in Arkansas, Kansas, and the basin of the Ohio. But the old theory that the mound-builders were a distinct race of highly civilized agriculturists, who had lived from remote antiquity in the regions of the mounds and were eventually exterminated by the nomadic hordes coming from the northward, represented to-day by the present Indians, is no longer supported by the principal American ethnologists, who hold that the Indians are their descendants.

In Ohio there are thousands of mounds, some in the form of circles, others four-sided, and in a few cases eight-sided. Sometimes a square and a circle are united. Altar-mounds, small rounded heaps of earth, are found in Ohio. At their centre is a basin-shaped mass of hard clay showing effects of fire. These basins are 3 or 4 ft. across, and contain ashes and charcoal. Upon these altars are found many objects.

The most famous mound in Ohio is the “Great-Serpent,” in Adams county. It lies upon a narrow ridge between three streams which unite. It is a gigantic serpent made in earth. Across the widely-opened jaws it measures 75 ft.; the body just behind the head measures 30 ft. across and is 5 ft. high; and, following the curves, the length is 334 ft. The front of the mound is an elliptical enclosure with a heap of stones at its centre. Beyond this is a form somewhat indistinct, thought by some to be a frog.

In Wisconsin the most interesting mounds are the effigy mounds—earthen forms of mammals, birds and reptiles—usually in groups and of gigantic size. Among them are buffalo, moose, elk, deer, fox, wolf, panther and lynx. Some panthers have tails 350 ft. long, and some eagles measure 1000 ft. from tip to tip of outspread wings. Occasionally the figures are cut or sunk in the earth, and near them are hundreds of simple burial mounds. It seems most probable that the purpose of these effigy mounds is totemic; but that they were objects of worship as guardians of the villages.

Further south in west Tennessee another class of mound is found. This contains graves made of slabs of stone set on edge. The simplest have six stones, two at the sides, two at the ends, one at the top and one at the bottom. Sometimes there is one of these graves in a mound, sometimes many. In one, 12 m. from Nashville, 45 ft. across and 12 ft. high, there were found, in a hundred skeletons, mostly in stone graves ranged one above the other, the skull in the upper graves had been buried stretched at full length. The lower graves were short and square, and the bones in them had been cleaned and piled in little heaps.

The mound-builders were Stone-Age men, and made many beautiful objects of stone, shell, bone and beaten metals, but they had no knowledge of smelting. That they were not one race is proved by a study of the skulls from the mounds.

MOUNDSVILLE, a city and the county-seat of Marshall county, West Virginia, U.S.A., on the Ohio river, 12 m., S. of Wheeling. Pop. (1900) 5632; (1910) 8918. It is served by the Baltimore & Ohio railroad, by an electric line to Wheeling and by boats to Pittsburgh, Columbus, and intermediate ports. Near Moundsville on the north of Grave Creek is Grave Creek Mound one of the largest relics of the “American mound-builders”; it is in the form of a regular cone, and is about 330 ft. in diameter at the base and 70 ft. in height. Two sepulchral chambers were discovered in it in 1838. In the upper chamber, about half-way between the centre of the base and the apex, was a single skeleton, adorned with beads, copper bracelets and plates of mica; in the lower chamber, directly under the upper and partly in the natural earth, were two skeletons, one adorned with beads and the other without ornament. On the sides and top of the lower chamber was a framework of timbers, which seems to indicate that the mound is of comparatively recent date. The city of Moundsville was formed in 1866 by the consolidation of the town of Moundsville (laid out on the Ohio river in 1831, and incorporated in 1832), and the town of Elizabethtown (laid out, about ½ m. from the river, in 1798, and incorporated in 1836).

MOUNET-SULLY, JEAN (1841– ), French actor, was born at Bergerac, on the 28th of February, 1841. He entered the Conservatoire at the age of twenty-one, and took the first prize for tragedy. In 1868 he made his début at the Odéon without attracting much attention. His career was interrupted by the Franco-Prussian War, and the liking he developed for soldiering had almost decided him to give up the stage, when he was offered the opportunity of playing the part of Oreste in Racine’s Andromaque at the Comédie Française in 1872. His striking presence and voice and the passionate vigour of his acting made an immediate impression, and the eventual result was his election as sociétaire in 1874. He became one of the mainstays of the Comédie Française, and distinguished himself in great variety of tragic and romantic parts. Perhaps his most famous impersonation was that of Don Juan in L’Odétoire, a part in which he was also successful in London and of Sophocles’s drama. This was first performed in the old Roman amphitheatre at Orange in 1888. Other prominent parts in Mounet-Sully’s répertoire were Achille in Racine’s Iphigénie en Aulide, Hippolyte in Phèdre, Hamlet, the title parts in Victor Hugo’s Hernani and Ruy Bias, Francis I. in Le Roi s’amuse, and Didier in Marion Delorme. He was created chevalier of the Legion of Honour in 1889. He also wrote a play, La Baveuse de larmes, and in 1906, in collaboration with Pierre Barbier, La Vieillesse de Don Juan in verse.

MOUVIER, JEAN JOSEPH (1755–1860), French politician, was born at Grenoble (Isère) on the 12th of November 1758. He studied law, and in 1783 obtained ajudgeship at Grenoble. He took part in the struggle between the t. and the court in 1788, and promoted the meeting of the estates of Dauphiné at Vizille (July 20, 1788), which on the eve of the Revolution created an immense stir. He was secretary of this assembly, and drafted the cahiers of grievances and remonstrances presented to it to the king. This led to his important election to the second estate of the states general of 1789. There, and in the Constituent Assembly, he was at first an upholder of the new ideas, pronouncing himself in favour of the union of the Third Estate with the two privileged orders, proposing the famous oath of the Tennis Court, assisting in the preparation of the new constitution, and demanding the return of Necker. On the 28th of September 1789 he was elected president of the Constituent Assembly. Being unable, however, to approve the proceedings which followed, Mounier withdrew to Dauphiné, gave in his resignation as deputy, and, becoming suspect, took refuge in Switzerland in 1790. He returned to France in 1801, was named by Bonaparte prefect of the department of Ille-et-Vilaine, which he reorganized, and in 1805 was appointed councillor of state. He died in Paris on the 28th of January 1806. His principal writings are Considérations sur les gouvernements (1790); Recherches sur les causes qui ont empêché les Français de devenir libres (1792), and De l’Influence attribué aux phénacées, aux ressus-maçons et aux illuminés sur la révolution de la France (1801).

MOUNT, WILLIAM SIDNEY (1807–1888), American artist, was born at Setauket, Long Island, New York, on the 26th of November 1807. He studied in the schools of the National Academy of Design, New York, and in 1832 was made a full Academician. Among his better-known works are “Turning

**MOUNTAIN** (O. Fr. montagne; popular Lat. montanea, an adjectival form from the classical *mons*, *montis*, whence Eng. "mount," a form usually used along with the name of an individual mountain, e.g. Mt Everest), a natural elevation of the earth’s surface. The term properly connotes height superior to that of a hill (O. Eng. *hüll*, cognate with Lat. *colis*); but the distinction depends on the prominence of a given elevation in relation to its surroundings, and in some degree to the bold or gentle character of its outline.

For the classification of mountains according to the various processes of their formation, see GEOGRAPHY, § Principles of Geography; and for further details GEOLOGY, § viii.

**MOUNTAIN, THE (La Montagne),** the name applied during the French Revolution to a political group, whose members, called Montagnards, sat on the highest benches in the Assembly. The term, which was first used during the session of the Legislative Assembly, did not come into general use until 1793. At the opening of the Convention the Montagnard group comprised men of very diverse shades of opinion, and such cohesion as it subsequently acquired was due rather to the opposition of its leaders to the Girondist leaders than to any fundamental hostility between the two groups. The chief point of distinction was that the Girondists were mainly theorists and thinkers, whereas the Mountain was composed almost entirely of uncompromising men of action. During their struggle with the Girondists, the Montagnards gained the upper hand in the Jacobin Club, and for a time Jacobin and Montagnard were synonymous terms. The Mountain was successively under the sway of such men as Marat, Danton, and Robespierre, and the group finally disappeared after Robespierre’s death and the successes of the French arms.

See also the articles Jacobins, Girondists and French Revolution.

**MOUNTAIN ASH,** an urban district of Glamorganshire, south Wales, in the Aberdare valley on the Cynon, a west bank tributary of the Taff, with stations on the Taff Vale and Great Western railways, 8½ m. N.E. of Cardiff. Pop. (1901), 31,093. A branch of the Glamorganshire canal passes through the place. At the beginning of the 19th century Mountain Ash was a small village known only by its Welsh name of Aberpenar, but from 1850, with the development of its collieries, the population rapidly increased. The district has an area of 10,504 acres and comprises; besides Mountain Ash proper, a string of villages, the chief being Cwmpenny, Penrhiwceiber, Abercyron or Aberdare Junction (at the confluence of the Cynon with the Taff) and Ynysybwl, 3 m. to the west on the Clydach. The public buildings include St Margaret’s (1862) and St Winifred’s (1883), the parish churches of Mountain Ash and Penrhiwceiber respectively; old and new town halls (1864 and 1904), hospital (1866), and a library institute and public hall erected in 1809, at a cost of £8,000, by the workmen of Nixon’s Navigation collieries. There is a park of 7½ acres given in 1805, by Lord Aberdare, whose residence, Duffryn, is in the district. There are also a workmen’s institute and a public hall at Penrhiwceiber. The older part of the urban district is included in the parliamentary borough of Merthyr Tydfil, and also shares with Merthyr and Aberdare the services of a stipendiary magistrate.

**MOUNTAINEERING,** the art of moving about safely in mountain regions, avoiding the dangers incidental to them, and attaining high points difficult of access. It consists of two main divisions, rock-craft and snow-craft. Rock-craft consists in the intelligent selection of a line of route and in gymnastic skill to follow the line chosen. In snow-craft the choice of route is the result of a full understanding of the behaviour of snow in the various conditions; it depends largely upon experience, and much less upon gymnastic skill. The dangers which the craft of climbing has been developed to avoid are of two main kinds: the danger of things falling on the traveler and the danger of his falling himself. The things that may fall are rocks, ice and snow; the traveler may fall from rocks, ice or snow, or into crevasses in ice or snow. There are also dangers from weather. Thus in all there are eight chief dangers: falling rocks, falling ice, snow-avalanches, falls from difficult rocks, falls from ice slopes, falls down snow slopes, falls into crevasses, dangers from weather. To select and follow a route avoiding these dangers is to exercise the climber’s craft.

**Falling Rocks.**—Every rock mountain is falling to pieces, the process being specially rapid above the snow-line. Rock-faces are constantly swept by falling stones, which it is generally possible to dodge. Falling rocks tend to form furrows in a mountain face, and these furrows (coulours) have to be ascended with caution, their sides being often safe when the middle is stoney. Stones fall more frequently on some days than on others according to the wave action of the weather. In some cases a valuable help on such a question. The direction of the dip of rock strata often determines whether a particular face is safe or dangerous; the character of the rock must also be considered. Where stones fall frequently débris will be found below, whilst on snow slopes falling stones cut furrows visible from a great distance. In planning an ascent of a new peak such traces must be looked for. When falling stones get mixed in considerable quantity with slushy snow or water a mud avalanche is formed (common in the Himalaya). It is necessary to avoid camping in their possible line of fall.

**Falling Ice.**—The places where ice may fall can always be determined beforehand. It falls in the broken parts of glaciers (seracs) and from overhanging cornices formed on the crests of narrow ridges. Large icicles are often formed on steep rock-faces, and these fall frequently in fine weather following cold and stormy days. They have to be avoided like falling stones. Seracs are slow in formation, and slow in arriving (by glacier motion) at a condition of unstable equilibrium. They generally fall or just after the most perfect part of the day, and their débris seldom comes free. By skillful observation the climbers usually devise a safe route through a most intricate ice-fall, but such places should be avoided in the afternoon of a hot day. Hanging glaciers (i.e. glaciers perched on steep slopes) often discharge themselves over steep rock-faces, the snow breaking off at intervals. They can always be detected by their débris below. Their track should be avoided.

**Snow Avalanches.**—These mainly occur on steep slopes when the snow is in bad condition, early in the year, or after a recent fresh fall. Days when snow is in bad condition are easily recognized; on such days it may be inadvisable to traverse snow-slopes which at another time may be as safe as a high-road. Beds of snow collected on rock-ledges in bad weather fall off when a thaw comes, and are dangerous to rock-climbers. Snow that has recently fallen upon ice slopes is always liable to slip off bodily. Such falling masses generally make the lower part of their descent by coulours. Snow avalanches never fall in unexpected places, but have their easily recognizable routes, which can be avoided in times of danger by experienced mountaineers.

In many cases, snow avalanches are caused by the climber in the desideratum by his choice of handhold and foothold, and his adhesion to those he has chosen. Much depends on a correct estimate of the firmness of the rock where weight is to be thrown upon it. Many loose rocks are quite firm enough to bear a man’s weight, but experience is needed to know which can be trusted, and skill is required in transferring the weight to them without jerking. On all difficult rocks the rope is the greatest safeguard for all except the first man in the ascent, the last in the descent. In such places a party of three or four men roped together, with a distance of 15 to 20 ft. between one and another, will be
able to hold up one of their number (except the top man) if one only moves at a time and the others are firmly placed and keep the rope tight between them, so that a falling individual may be arrested before his velocity has been accelerated. In very difficult places help may be obtained by throwing a loose rope round a projection above and pulling on it; this method is specially valuable in a difficult descent. The rope usually employed is a strong Manila cord called Alpine Club rope, but some prefer a thinner rope used double. On rotten rocks the rope must be handled with special care, lest it should start loose stones on to the heads of those below. Similar care must be given to handholds and footholds, for the same reason. When a horizontal traverse has to be made across very difficult rocks, a dangerous situation may arise unless at both ends of the traverse there be firm positions. Even then the end men gain little from the rope. Mutual assistance on hard rocks takes all manner of forms: two, or even three, men climbing on one another’s shoulders, or using for foothold an ice-axe propped up by others. The great principle is that of co-operation, all the members of the party climbing with reference to the others, and not as independent units; each when moving must know what the man in front and the man behind are doing, and both must be constantly aware of a vencer of ice (serrglas), which may even render them inaccessible. Climbing-irons, crampons, steigeisen are useful on such occasions.

Ice Slopes.—Climbing-irons are also most useful on ice or hard snow, as by them step-cutting can sometimes be avoided, and the footing at all times rendered more secure. True ice slopes are rare in Europe, though common in tropical mountains, where newly-fallen snow quickly thaws on the surface and becomes sodden below, so that the next night’s frost turns the whole into a mass of solid ice. An ice slope can only be surmounted by step-cutting. For this an ice-axe is needed, the common form being a small pick-axe on the end of a pole as long as from the elbow of a man to the ground. This pole is used also as a walking-stick, and is furnished with a spike at the foot.

Snow Slopes are very common, and usually easy to ascend. At the foot of a snow or ice slope is generally a big crevasse, called a bergschrund, where the final slope of the mountains rises from a snow-field or glacier. Such bergschrunds are generally too wide to be stirred, and must be crossed by a snow bridge, which needs careful testing and a painstaking use of the rope. A steep snow slope in bad condition may be dangerous, as the whole body of snow may start as an avalanche. Such slopes are less dangerous if ascended directly than obliquely, for an oblique or horizontal track cuts them across and facilitates movement of the mass. New snow lying on ice is specially dangerous. Experience is needful for deciding on the advisability of advancing over snow in doubtful condition. Snow on rocks is usually rotten unless it be thick; snow on snow is likely to be sound. A day or two of fine weather will usually bring new snow into sound condition. Snow cannot lie at a very steep angle, though it often deceives the eye as to its slope. Snow slopes seldom exceed 40°. Ice slopes may be much steeper. Snow slopes in early morning are usually hard and safe, but the same in the afternoon are quite soft and possibly dangerous; here the advantage of an early start.

Crevasses.—These are the slits or deep chasms formed in the substance of a glacier as it passes over an uneven bed. They may be open or hidden. In the lower part of a glacier the crevasses are open. Above the snow-line they are frequently hidden by arched-over accumulations of winter snow. The detection of hidden crevasses requires care and experience. After a fresh fall of snow they can only be detected by sounding with the pole of the ice-axe, or by looking to right and left where the open extension of a partially hidden crevasse may be obvious. The safeguard against accident is the rope, and no one should ever cross a snow-covered glacier unless roped to one, or better to two, companions.

Weather.—The main group of dangers caused by bad weather centre round the change it effects in the condition of snow and rock, making ascents suddenly perilous which before were easy, and so altering the aspect of things as to make it hard to find the way or retrace a route. In storm the man who is wont to rely on a compass has great advantage over a merely empirical follower of his eyes. In large snow-fields it is, of course, easier to go wrong than on rocks, but a trained intelligence is the best companion and the surest guide.

History.—The first recorded mountain ascent after Old Testament times is Trajan’s ascent of Etna to see the sun rise. The Roche Melon (11,600 ft.) was climbed in 1358. Peter III. of Aragon climbed Canigou in the Pyrenees in the last quarter of the 13th century. In 1339 Petrarich climbed Mt Ventou near Vaucurse. In 1402 the ascent of Mt Aiguille was made by order of Charles VIII. of France. The Humanists of the 16th century adopted a new attitude towards mountains, but the disturbed state of Europe nipped in the bud the nascent mountaineering of the Zürich school. Leonardo da Vinci climbed to a snow-field in the neighbourhood of the Val Sesia and made scientific observations. Konrad Gesner and Josias Simler of Zürich visited and described mountains, and made regular ascents. The use of axe and rope were locally invented by the Swiss. No great rock-climbing party was formed in the 17th century. In 1744 the Titlis was climbed—the first snow-mountain. Pococke and Windham’s historic visit to Chamonix was made in 1741, and set the fashion of visiting the glaciers. The first attempt to ascend Mont Blanc was made in 1775 by a party of natives. In 1786 Dr Michel Paccard and Jacques Balmat gained the summit for the first time. De Saussure followed next year. The Jungfrau was climbed in 1811, the Finsteraarhorn in 1812, and the Zermatt Breithorn in 1813. Thenceforward tourists showed a tendency to climb, and the body of Alpine guides began to come into existence in consequence. Systematic mountaineering, as a sport, is usually dated from Sir Alfred Wills’s ascent of the Wetterhorn in 1854. The first ascent of Monte Rosa was made in 1855. The Alpine Club was founded in London in 1857, and soon imitated in most European countries. Edward Whymper’s ascent of the Matterhorn in 1865 marks the close of the main period of Alpine conquest, during which the craft of climbing was invented and perfected, the body of professional guides formed and their traditions fixed. Passing to other ranges, the exploration of the Pyrenees was concurrent with that of the Alps. The Caucasus followed, mainly owing to the initiative of D. W. Freshfield; it was first visited by exploring climbers in 1868, and most of its great peaks were climbed by 1888. Trained climbers turned their attention to the mountains of North America in 1888, when the Rev. W. S. Green made an expedition to the Selkirk. From that time exploration has gone on apace, and many English and American climbing parties have surveyed most of the highest groups of snow-peaks; Pike’s Peak (14,147 ft.) having been climbed by Mr E. James and party in 1820, and Mt Saint Elias (18,024 ft.) by the duke of the Abruzzi and party in 1897. The exploration of the highest Andes was begun in 1879–1880, when Whymper climbed Chimborazo and explored the mountains of Ecuador. The Cordillera between Chile and Argentina a route was opened in 1878, 1885, and 1887. The Andes of Bolivia were explored by Sir Martin Conway in 1880. Chilean and Argentine expeditions revealed the structure of the southern Cordillera in the years 1885–1886. Sir Martin Conway visited the mountains of Tierra del Fuego in 1886. The Alps of New Zealand were first attacked in 1882 by the Rev. W. S. Green, and shortly afterwards a New Zealand Alpine Club was founded, and by their activities the exploration of the range was pushed forward. In 1895 Mr E. A. Fitzgerald made an important journey in this range. Of the high African peaks, Kilimanjaro was climbed in 1889 by Dr Hans Meyer, Mt Kenya in 1889 by J. E. S. Mackinder, and a peak of Ruwenzori by H. J. Moore in 1900. The Asiatie moun- tains have as yet been little climbed, though those that lie west of the British Empire have been surveyed. In 1892 Sir Martin...
Conway explored the Karakoram Himalayas, and climbed a peak of 23,000 ft. In 1895 A. F. Munnery made a fatal attempt to climb Namjagbarwa, whilst in 1900 D. W. Freshfield took an expedition to the snow regions of Sikkim. In 1892, 1903, 1906 and 1908 Fannie Bullock Workman made ascents in the Himalayas, including one of the Kun Kun peaks (23,300 ft.). A body of Gurkha sepoy was trained as expert mountainiers by Major the Hon. C. G. Bruce, and a good deal of exploration has been accomplished by them. The only mountains of the northern polar region that have been explored are those of Spitzbergen by Sir Martin Conway's expeditions in 1896 and 1897, and the peaks in the north of Norway and the Lofoten by various Alpine Club and Norwegian parties.

**MOUNT BARTER,** a town of Hindhears county, South Australia, at the foot of the mountain of the same name, 345 m. by rail E. of Adelaide. It has an extremely fine climate and is much frequented as a health resort in summer. It is the centre of a populous and fertile district producing quantities of fruit, wheat and dairy produce, important cattle sales are held weekly, and there are several engineering works, flour mills and tanneries in the town, which also is the seat of a wattle-bark industry. Pop. about 2000; but the inhabitants of the Mount Barker district number over 34,000.

**MOUNT CARMEL,** a borough of Northumberland county, Pennsylvania, U.S.A. It is situated on the island of Shamokin Creek, about 500 ft. N.E. of Harrisburg. Pop. (1800), 854; (1900), 13,170, of whom 3772 were foreign-born; (1890 census) 17,532. It is served by the Lehigh Valley, the Philadelphia & Reading, and the Shamokin Division of the Northern Central (Pennsylvania system) railways. Anchise coal abounds here, and the mining and shipping of it, together with the manufacture of mining machinery and miners' supplies are the borough's principal industries. This locality was settled late in the 18th century. About 1848 Mount Carmel was laid out as a town, and in 1862 was chartered as a borough.

**MOUNT CLEMENS,** a city and the county seat of Macomb county, Michigan, U.S.A., on Clinton river, about 5 m. (about 2m. in direct line) from its entrance into Lake Saint Claire, and 20 m. N. by E. of Detroit. Pop. (1870) 4748; (1890) 6576 (1104 foreign-born); (1900, state census) 7108; (1910) 7707. It is served by the Grand Trunk railway and by two electric lines to Detroit. The waters of Mount Clemens are beneficial to patients suffering from rheumatism, blood diseases and nervous disorders. The city's principal manufactures are beet sugar, barrels and other cooperage products, wagons, carriages, sleighs and agricultural implements. Mount Clemens was settled in 1802, was incorporated as a village in 1837, and was chartered as a city in 1879.

**MOUNT DESERT,** an island in Hancock county, Maine, U.S.A. It is about 16 m. long and 10 m. wide in its widest part, with an approximate area of 100 sq. m. and a population (1910) of 8014. The Maine Central railroad runs a ferry from its nearest station on the mainland (Mount Desert Ferry), and the island is also accessible during the warmer months by steamship lines from New York, Boston, Portland, and several other ports. On the north across Mount Desert Narrows, a bridge connects the island with the mainland. Eagle Lake, at the north-east base of Green Mountain, is a beautiful sheet of water about 24 m. long, and 3 m. wide, and Great Pond, 4 m. long, lies near Somesville between Beech Hill and Western Mountain. There are numerous outlying rocky islands. The surface of Mount Desert is generally so rocky that the greater part of it has never been inhabited or cultivated, but where there is a thin soil the hills are wooded with spruce, alder, birch, maple and mountain ash. The hilly scenery, the cool summer climate, and the facilities for boating and fishing attract many thousands of visitors each summer, and the maintenance of the permanent population is derived very largely from the summer residents. The Penobscot and Passamaquody Indians come here in the season to sell their basket-work, toy canoes, moccasins, bows and arrows, &c. The villages most frequented by summer visitors are Bar Harbor (q.v.) on the north-east coast; Northeast Harbor, Southwest Harbor and Seal Harbor on the south coast; and Somesville, at the head of Somes Sound. Along the western shore are several quaint old hamlets.

Mount Desert Island was discovered and named by Samuel de Champlain on the 5th of September 1604. French Jesuits established a settlement, St Sauveur, at the entrance to Somes Sound in 1609, but this was destroyed four years later by Samuel Argall. In 1688 the island was granted by Louis XIV. to Sieur de la Mothe Cadillac, but no permanent settlement was established until 1762, when the general court of Massachusetts granted one-half of the island to Governor Francis Bernard and under his encouragement a settlement was begun at Southwest Harbor. During the War of Independence all the American estates of Bernard were confiscated, but in 1785 his former interest in Mount Desert was conveyed to his son, John, and two years later heirs of Cadillac, among them his granddaughter, Mme de Gregory, who had come to Maine in 1786, received from the general court a grant for the remaining portion. Until the summer visitors came, the settlers gained only a scantly livelihood, chiefly by fishing, lumbering, boat building and farming. Practically all of them lived along the shore; they had boats, but few horses, and the roads were only rough trails. There is no record of any mail service until 1820, and as late as 1870 the only means of reaching the island was by stage from Bangor or by steamboat twice a week from Portland.

See George E. Street, *Mount Desert, a History* (Boston, 1905).

**MOUNTEBANK** (Ital. montambnico, montimbanco, from montare, to climb up on, mount, and dance, bench, cf. saltimbancio, an acrobat or dancer, one who dances or leaps on a bench), a wandering juggler, story-teller, seller of quack medicines, &c., who performs his entertainment on a platform or raised bench, hence any charlatan or quack.

**MOUNTED INFANTRY,** infantry soldiers who ride instead of marching on foot from one place to another. As combatants they are infantry pure and simple, being neither armed nor trained to fight on horseback, and their special characteristic is the power to move from one point to another with great rapidity. They are therefore useful (a) in wars, such as colonial wars, in which cavalry proper finds no scope for its activity, and (b) in performing duties for which mounted troops, but not necessarily cavalry that can fight mounted, are required. In these two roles the mounted infantry contribute to the reserve forces, from which cavalry is both a most expensive arm and one which cannot be improvised, there is an ever-recurring tendency in all armies to consider it as being more ornamental than useful, and in consequence to substitute mounted infantry under one name or another (the original droguins for example were mounted infantry) for "shock action" cavalry. In recent times, owing to the development of the long-ranging magazine rifle, this tendency has been intensified to such a degree that Russia, for example, converted the whole of her cavalry into droguins—the term being used in its old sense—and trained it to act dismounted in large bodies. It is however significant of the failure of this wholesale conversion that after the Russo-Japanese War the regiments that were formerly hussars and lancers were reorganized as such and ceased to be styled and trained as droguins.

It is difficult, but at the same time important, to differentiate between droguins or "mounted rifles," as they are often called to-day, and mounted infantry in a narrower sense of the word.
Mounted rifles are half cavalry, mounted infantry merely specially mobile infantry. The American cavalry in the Civil War, the Boers in the South African War, the Russians in the Manchurian campaign—were mounted rifles, and the question of their advantages and disadvantages, as compared with what is generally called "regular" cavalry, is purely a cavalry one. The main question as regards mounted infantry is whether its existence as a special arm is justified by the kind and degree of assistance which it is peculiarly qualified to give to the other arms in war. If this be answered in the affirmative for a particular army, then that army, having raised mounted infantry, may require of it such additional services as it would be more or less uneconomical to assign to regular cavalry. Mounted infantry in this case may and in fact does assume the rôle of mounted rifles; for example, in the British regular army the duties of divisional mounted troops are performed by mounted infantry, while in the territorial army the same duties are performed by yeomanry mounted rifles.

In the British mounted infantry, which is the only force in any army specially trained as such, the course of instruction lasts four months and is based on the assumption that officers and men under instruction are already fully trained as infantry. (M.I. Training, 1909). All words of command, bugle sounds, formations, &c., are similar to those used in the infantry, and as a rule spurs are forbidden. The mounted infantry horse is a handy cob (14-2 to 15). The organization adopted is by battalions and companies, each company having 6 officers and 153 men, and the battalion consisting of three such companies and a machine-gun section. Mounted infantry battalions and companies do not exist in peace, but are formed on mobilization from the qualified men available who can be spared from the infantry. Since many more men are trained than would be required for the 24 or 26 companies forming part of the expeditionary force, the arm is capable of considerable expansion, while the men first selected for the service are in every way picked men. As already mentioned its duties are (a) with respect to the cavalry, first to assist and secondly to supplement or replace it—by the judicious use of the rifle, and (b) with respect to the infantry to relieve the unmounted man as far as possible of reconnoitring and orderly duties, and above all of the necessity of hurried and exhausting movements to seize points of support.

Cyclists.—The application of the bicycle to military purposes was first suggested in Great Britain, and military cycling became the special and almost exclusive property of the volunteer force, in which, when cycling became universally popular and the machines cheap, practically all battalions had sections and most of them companies of cyclists. In those days, however, the want of a common organization separated the yeomanry from the volunteers, and the latter, possessing no mounted troops of its own, employed its numerous cyclists in reconnoitring, protective and orderly work indifferently. Provisional battalions were frequently formed, and in spite of their heterogeneous composition and inadequate staff they proved capable of manoeuvring as units. Movements in brigade were practised at Aldershot in 1901, the brigade composed of 3 battalions of about 650 rifles each, drawn from some forty volunteer infantry units under training at the time, being trained in combined movements by parallel roads and night marching, as well as in field operations. When the fusion of the yeomanry and volunteers in the territorial force (1907–1908) released cyclists from the duties of mounted troops which had hitherto been imposed on them, the cyclist companies in the infantry battalions were disbanded, and their place taken by 10 cyclist battalions specially trained for protective work in large tactical bodies. The regular army, which is generally employed in almost roadless countries, only maintains a few cyclists for orderly work.

Amongst the regular armies that of France was certainly the pioneer in the matter of cycling. Infantry support for cavalry is a fundamental principle of the French doctrine of tactics, and this infantry support in so well-roaded a country as France naturally takes the form of strong cyclist groups. The French military cyclists are equipped with a folding bicycle, which allows of cross-country movement being undertaken without leaving the bicycles unguarded. In Germany very few military cyclists are maintained—one small section in each infantry or cavalry regiment. The field service regulations permit the grouping of these sections for united action as a company, but only under special circumstances. In Italy, however, whole battalions of the fast-moving light troops, Bersaglieri, have been within recent years provided with the cycle.

Cyclists are mounted infantry in the strictest possible sense of the phrase. They possess over all horsemen the incalculable advantages of being able to make longer marches; for they can cover 80 or 90 m. a day for several days; of exemption from forage anxieties; of freedom from the necessity in action of leaving one-third or one-quarter of the men to hold the horses; and of actual speed, an ordinary cyclist being able to move faster along a good road than a staff officer mounted on a thoroughbred. On the other hand, it is true that they may be as free to move across country as horsemen; a cyclist column, owing to its speed and great length in proportion to its numbers, is peculiarly liable to surprise; and the condition of the roads or a strong head wind materially reduces its rate of marching.

MOUNTFORT, WILLIAM (c. 1664–1692), English actor and dramatic writer, was the son of a Staffordshire gentleman. His first stage appearance was with the Dorset Garden company about 1678, and by 1682 he was taking important parts, usually those of the fine gentleman. Mountfort wrote a number of plays, wholly or in part, and many prologues and epilogues. He married, in 1686, Susanna Percival (see VERRUGGEN, MRS), the actress. Owing to jealousy of Mrs Bracegirdle's supposed interest in Mountfort, Captain Richard Hill, an adventurer, who had annoyed her with persistent attentions, accompanied by Charles, fifth Baron Mohun, murdered Mountfort in Howard Street, Strand, on the 9th of December 1692. Hill made his escape. Lord Mohun was tried by his peers and acquitted by a vote of 9 to 14.

MOUNT GAMBIER, a town of Grey county, South Australia, 305 m. by rail S.E. of Adelaide. It stands on the northern base of the mountain of the same name, an extinct volcano. It is a handsome town with many fine buildings of white limestone and grey and red dolomite, which abound in the neighbourhood, the church of St Paul being the finest edifice of its kind outside Adelaide. The agricultural society has a good showground where two shows are held annually. Two splendid lakes lie near the town—Blue Lake, 160 acres in extent, and Valley Lake, 97 acres, from the first of which the water-supply of the town is derived. Mount Gambier is the centre of one of the richest grain-growing districts in Australia. Pop. (1901), 3162; and including the suburbs, about 6000.

MOUNT HOLYOKE COLLEGE, the pioneer institution in America for the higher education of women, situated in the village of South Hadley, Massachusetts, near Mount Holyoke. It was founded by Margaret (Dwight), a wealthy lady of English stock, and called as Mount Holyoke Female Seminary in 1837 (opened in 1837), but the name was changed to Mount Holyoke College in 1893. Besides the recitation halls and laboratories there are the Dwight Memorial art building (1901), a library building (1905), the John Payson Williston observatory, botanical gardens (1901), a gymnasium, a hospital, and seven residence halls. For undergraduates the college offers two years of work in prescribed courses in Latin, Greek, French, German, English, history, Biblical literature, foreign language, physics, and chemistry, and two years of work in elective courses; for graduates it offers one year of advanced work, including courses in education designed for those preparing to teach. To make college expenses

---

1 The infantry "mounted scouts" of the Russian and French armies are simply auxiliaries and have no existence apart from their regiments.

2 The loss of men by accidents to the machines, punctures, &c., has been shown in manoeuvres to be nearly negligible.
in his favour in 1618, when he was created Baron Mountjoy, of Mountjoy Fort, Co. Tyrone, in the peerage of Ireland; and Baron Mountjoy of Thurstaston, Derbyshire, in the peerage of England. In 1628 he was further created earl of Newport in the Isle of Wight. In the same year he was appointed to command, with the rank of rear-admiral, the expedition for the relief of Rochelle; in 1629 he was made master of the ordnance.* He took the popular side at the beginning of the trouble between Charles I. and the parliament, and was an eager opponent of Strafford. When the Civil War broke out, however, Newport served in the royalist army, and took part in the second battle of Newbury in 1644. In January 1646 he was arrested as a prisoner and confined in London on parole. He died at Oxford on the 12th of February 1666, leaving two surviving sons, who in turn succeeded to the earldom of Newport and barony of Mountjoy. Both titles became extinct on the death of Henry, the younger of these sons, in 1681.

In 1683 Sir William Stewart (1633-1692), who owned large property in the counties of Donegal and Tyrone, and whose grandfather had created a baronet in 1623, was raised to the peerage of Ireland as Baron Stewart of Ramelton, Co. Donegal, and Viscount Mountjoy. Having served abroad, Mountjoy returned to Ireland in 1687, where he became brigadier-general. At the revolution he remained loyal to James II.; being a Protestant he was distrusted by Tyrconnel, the viceroy, and was removed with his troops from Londonderry to Dublin. When the gates of Londonderry were closed against James's representatives, Tyrconnel sent Mountjoy and Robert Lundy with a force to the north. After negotiations which resulted in Lundy being admitted as governor to the city, Mountjoy was sent with Sir Stephen Rice to Paris to report on the state of affairs to James II. On their arrival, Rice acting on secret instructions, denounced Mountjoy as a traitor, and the latter was thrown into the Bastille, where he remained till 1692. He then went over to William III., and was killed at Steinkirk on the 3rd of August 1692.

William, 3rd Viscount Mountjoy (1709-1790), was in 1745 created earl of Blesington, his mother having been sister and sole heiress of Charles, 2nd and last Viscount Blesington. On his death without issue in 1790 all his titles became extinct. Anne Stewart, daughter and heiress of Alexander Stewart, second son of the above-mentioned William, 1st Viscount Mountjoy, married Luke Gardiner, vice-treasurer of Ireland; and her grandson, Luke Gardiner (1744-1798), who inherited a large portion of the Mountjoy family estates, was created Baron Mountjoy of Mountjoy, Co. Tyrone (1790), and Viscount Mountjoy (1795), both in the peerage of Ireland; but on the death without male issue in 1829 of his son Charles John, who in 1816 was created earl of Blesington, all these titles again became extinct.

Thomas Windsor, of Hickman-Windsor (c. 1670-1738), second son of Thomas, Lord Windsor de Stanwell, 1st earl of Plymouth, was in 1690 created Viscount Windsor of Blacklace, in the peerage of Ireland. In 1712 he was created a peer of Great Britain with the title of Baron Mountjoy of the Isle of Wight, being descended in the female line from Sir Andrew Windsor (c. 1475-1543), 1st Baron Windsor de Stanwell, who married Elizabeth Blount, sister and co-heir of Edward, 2nd Baron Mountjoy of the first creation, who died an infant in 1475. On the death of Thomas's son Herbert in 1758 the title of Mountjoy again became extinct; but it was revived in favour of John Stuart, earl of Bute, who married Charlotte Jane Hickman-Windsor, Herbert's daughter and sole heiress, and who in 1790 was created Viscount Mountjoy of the Isle of Wight, earl of Windsor, and marquess of the county of Bute, all of which titles are held by his descendant, the present marquess of Bute.

MOUNTMELlick—Mount Vernon

MOUNTMELlick, a market town of Queen's county, Ireland, pleasantly situated on the Owenass (an affluent of the Barrow) which nearly encircles it. Pop. (1901), 2,407. It is the northern terminus of a branch of the Great Southern & Western railway, 73 m. N. of Maryborough and 58½ W.S.W. of Dublin. A branch of the Grand Canal also reaches the town, providing water communication with Dublin, and with Waterford by the river Barrow. There are industries of malting, tanning, woollen and salt manufactures, and iron-founding. A settlement of Quakers has contributed largely to the prosperity of the town. A provincial school of the Leinster Society of Friends was founded here in 1796.

MOUNT MORGAN, a municipality of Raglan county, Queensland, Australia, 28 m. by rail S.S.W. of Rockhampton. Pop. (1901), 6280. Railway communication was opened in 1898. The town has been considered to be on the richest gold site in Australia, the gold being very fine and pure.

MOUNT SORrel, a market town in the Loughborough (Mid) parliamentary division of Leicestershire, on the river Soar, 7 m. N. of Leicester. Pop. (1901), 2417. The Sileby station on the Midland main line lies 1½ m. E. The position is beautiful, a steep hill, once owned by the castle, rising above the wooded valley. At Barrow-Upon-Soar, 2 m. N. (pop. 2495; Barrow and Quorn railway station), lime is worked extensively. The village of Quorn or Quorn, 63 m. N.W., is the head-quarters of the well-known Quorn hunt. Quornlon is an urban district (pop. 2173).

MOUNT Stephen, George Stephen, Baron (1826- ). Canadian financier, was born on the 18th of June 1829 at Dufftown, Banffshire, Scotland, the son of William Stephen and Elspeth Smith. He was educated at the parish school, after which he was for a time a herd boy. In 1850 he went to Canada and soon became a prominent business man in Montreal. In 1878 he joined with his cousin, Donald Smith (afterwards Lord Strathcona), in the purchase of the St. Paul & Pacific railway. This led to his interest in the development of western Canada, and from 1881 onwards he was associated with his cousin in the construction of the Canadian Pacific railway, for his services in connexion with which he was in 1886 made a baronet, in 1891 raised to the peerage; and in 1905 made G.C.V.O. In 1888 he left Canada, and thereafter lived in England and Scotland. He gave lavishly to charity and education, and with Lord Strathcona built and endowed the Royal Victoria hospital at Montreal.

MOUNT-TEMPLE, William Francis Cowper-Temple, Baron (1811-1888), English politician, second son of the 5th Earl Cowper, was born at Brocket Hall, Hertfordshire, on the 13th of December 1811. He was educated at Eton, and entered the Royal Horse Guards, attaining the rank of brevet-major in 1852. His mother, Emily Mary, was sister to the prime minister, Lord Melbourne, whose secretary William Cowper became in 1835; in this year he entered parliament as member for Hertford, which he continued to represent until 1863. As commissioner of works (1860-1866) he carried the bills for the Thames Embankment (1862), and for the new law courts (1863); but he is best known for the amendment, known as the “Cowper-Temple clause,” which he introduced into the second reading of the Education Bill of 1870, that no catechism nor denominational teaching of any kind should be included in the religious instruction given in rate-aided schools. His mother died in 1868, and Lord Palmerston, as her second husband, died in 1869, and under his stepfather's will William Cowper succeeded to some of the Palmerston estates in Ireland and Hampshire, and assumed the additional name of Temple. He was M.P. for South Hampshire from 1858 until 1880 when he was raised to the peerage as Baron Mount-Temple of Mount-Temple, Sligo. He died at Broadlands, near Romsey, on the 16th of October 1888. He was twice married, but left no children, the Palmerston estates descending to the Right Hon. Evelyn Ashley (1836-1907), who was under-secretary of state for the colonies from 1882 to 1885.

MOUNT VERNON, a city and the county-seat of Jefferson county, Illinois, U.S.A., about 75 m. E. by S. of St. Louis. Pop. (1890), 3233; (1900), 5166; (1910), 8007. It is served by the Chicago & Eastern Illinois, the Louisville & Nashville, the Wabash, Chicago & Western, and the Southern railways. It is the headquarters of the fourth appellate court district of the state. Mount Vernon was settled in 1819, incorporated as a village in 1837 and chartered as a city in 1872. Many of its buildings were destroyed by a cyclone on the 19th of February 1888.

MOUNT VERNON, a city and the county-seat of Posey county, Indiana, U.S.A., on the Ohio river, in the extreme south-west corner of the state. Pop. (1890), 4705; (1900), 5124; (1910, u.census), 6280. Mount Vernon is served by the Evansville & Terre Haute, the Louisville & Nashville, and the Evansville & Mount Vernon (electric) railways. The city is a trading centre for the surrounding farming region. It has a valuable river trade, and various manufactures. The first settlement here was made in 1803, and in 1819 a town was laid out and named Mount Vernon. It became the county-seat in 1825, and was incorporated as a town in 1846 and chartered as a city in 1865.

MOUNT VERNON, a town of Linn county, Iowa, U.S.A., 16 m. E. of Cedar Rapids. Pop. (1900), 1629; (1910, u.census), 1532. Mount Vernon is served by the Chicago & North Western railway. It is the seat of Cornell College (Methodist Episcopal; coeducational), which was opened as the Iowa Conference Seminary in 1853, and was chartered in 1857 under its present name, adopted in honour of William W. Cornell (1823-1870), an iron manufacturer of New York City and a benefactor of the institution. Cornell College includes a collegiate department, an academy, a conservatory of music, a school of art, a school of oratory and a summer school; in 1907-1908 it had 40 instructors and 755 students. Mount Vernon was settled in 1842, was laid out in 1847, and was incorporated as a town in 1860.

MOUNT VERNON, a city of Westchester county, in south-eastern New York, U.S.A., on the Bronx river and Eastchester Creek, 13 m. from the Grand Central station, New York City. Pop. (1890), 20,830; (1900), 20,346, of whom 5265 were foreign-born (many being Italians) and 316 negroes; (1910, census), 30,919. It is served by the New York Central & Hudson River and the New York, New Haven & Hartford railways, and by electric lines to New York City, Yonkers, New Rochelle, &c. The city has various manufactures, but in the main is a residential suburb of New York; the finest residences are in the eastern, central and north-eastern sections, the last being known as Chester Hill; the foreign-born element is largely concentrated in the western part. Mount Vernon is in the township of Eastchester, which was settled from Connecticut in 1664, possibly in the hope of pushing Connecticut's boundary nearer the Hudson. It was called "Ten Farms" or Eastchester. A parish of the same name was established in 1693, but was disallowed in England. About 1682 the "Ten Farmers" established a free school. In 1764 the foundations were laid of the present St. Paul's (Protestant Episcopal), which was used through a part of the American War of Independence as a British military hospital. St Paul's churchyard dates back to the close of the 17th century. Along the White Plains road (now Lincoln Avenue) Washington retreated, pursued by General Henry Clinton, before the battle of White Plains in 1776. The city of Mount Vernon was founded in 1851 by several reality companies. The postal authorities objected to the name Monticello, originally used, and Mount Vernon was adopted instead. Mount Vernon was incorporated as a village in 1853 and was first chartered as a city in 1892. West Mount Vernon was founded by the Teutonic Homestead Association and was annexed to Mount Vernon in 1860.

942
MOUNT VERNON—MOUSE

MOUNT VERNON, a city and the county-seat of Knox county, Ohio, U.S.A., on the Kokosing river, about 45 m. N.E. of Columbus. Pop. (1800), 6027; (1806), 6733, including 259 foreign-born and 239 negroes; (1810), 9087. Mount Vernon is served by the Baltimore & Ohio and the Cleveland, Akron & Columbus, railways. The city is the seat of the state hospital for tuberculosis, has a fine court-house, a public library, and various manufacturing establishments. Natural gas is found in the vicinity. Mount Vernon was laid out in 1803; it became the county-seat in 1807, was incorporated as a town in 1845, and became a city in 1853.

MOUNT VERNON, the former home of George Washington, in Fairfax county, Virginia, U.S.A., on the Potomac river, 15 m. below Washington, D.C., reached by steamer from the railroad station of Alexandria, Virginia. The mansion-house, which is the centre of interest, stands on a bluff overlooking the river. The house is built of wood, but the siding is of wide thick boards so panelled as to give the appearance of cut and dressed stonework. The rooms contain much of the furniture which was in them when they were occupied by General Washington and his family; and the furniture that had been lost has been in part replaced by other furniture of historic interest and of the style in use in Washington's day. In the main hall hangs a glass cask containing the key to the Bastille which Washington received from Lafayette in 1790. From each of the houses a curved colonnade and a pavilion lead westly to a row of out-buildings which partially enclose a bowling green. These have since been cleared of their old shrubs and walks, and beautiful gardens (with trees planted by Washington, Franklin, Jefferson, Lafayette and others). A short distance south-west of the mansion-house and between it and the wharf is a plain brick tomb, which was built by Washington's direction on a site chosen by himself, and contains the remains of Washington and Mrs Washington (removed to this tomb from the old family vault in 1831), and of about thirty relatives—members of the Washingtons, Blackburn, Corbin, Bushrod, Lewis and Custis families.

The estate, originally called "Little Hunting Creek Plantation," was devised in 1766 by John Washington (the first of this family in America) to his son, Lawrence, who in turn devised it to his daughter, Mildred, by whom (and her husband Roger Gregory) it was deeded in 1776 to his brother Augustine (George Washington's father). On Augustine's death (1743) it passed to Lawrence (George's half-brother), who built in 1743 the villa which forms the middle portion of the present mansion-house and named the estate Mount Vernon, in honour of his former commander, Admiral Edward Vernon (1664-1757). Lawrence left it (1752) to his widow Anne Fairfax (who in the same year married George Lee) with the proviso that it should pass at her death to George Washington, who meanwhile rented the estate, gaining full possession at her death in 1761. In 1764-1765 he enlarged the villa into the mansion-house and with its present dimensions by building an addition at each end, erected several of the out-buildings, and adorned the grounds, all according to his own plans and specifications. At General Washington's death (1799) Mount Vernon passed to his widow; at her death (1802) it passed to his nephew, Bushrod Washington, and at Bushrod Washington's death (1810) to his nephew John Augustine Washington, who devised it in 1813 to his widow, by whom it was devised in 1835 to their son John A. Washington. This last was authorized by his father's will to sell the estate to the United States government, and in 1847 offered the property for $100,000, but the offer was refused. In 1850 the mansion-house and 200 acres of the original estate, fast falling into decay, were bought for $200,000 (much of which had been raised through the efforts of Edward Everett) by the Mount Vernon Ladies' Association of the United States. This association under its charter (1856) bound itself to restore the estate to such a condition in which it was in the lifetime of Washington and to keep it sacred to his memory, and Virginia agreed to exempt it from taxation as long as these terms were fulfilled.

See B. J. Lossing, The Home of Washington: or Mount Vernon and its Associations (Hartford, 1870).

MOURNING (from the verb "to mourn", to be sorrowful, O. Eng. mearn; cf. O.H.G. morhun, Goth. maearun, to be anxious, O.N. morno, to pine away; by some referred to root seen in Gr. μπαμπα, sorrow, by others to root mor-, to die), the expression of grief or sorrow particularly for the dead; more specifically the outward or conventional signs of such grief. The public exhibition of this grief for the dead has taken various forms among different races and in different ages, from shoving of the head, or allowing the beard and hair to grow, from disfiguring the face and uttering loud wailing cries, to the wearing of clothes of a particular colour, now among Western races usually black, and to the purely conventional custom of using black-edged note-paper, cards, &c. (See further FUNERAL RITES.)

MOUSE, in its original sense probably the name of the semi-domesticated house-mouse (Mus musculus), the type of the genus Mus and of the family Muridae. Zoologically, there is no distinction between mice and rats; these names being employed respectively for most or all of the smaller and larger "mouse-like" and "rat-like" representatives of the Muridae, whether they belong to the genus Mus or not. It is true indeed that in zoological nomenclature some of these are distinguished as "voles" (see VOLE), but this is not in accord with popular usage, where such creatures come under the designation either of water-rats or field-mice. The distinctive characters of the typical mice (and rats), i.e. those included in the genus Mus, are dealt with in the article RODENTIA. With the exception of Madagascar, the genus Mus ranges over practically the whole of the Old World, having indigenous representatives even in Australasia; while the house-mouse, with man's involuntary aid, has succeeded in establishing itself throughout the civilized world. The following is a brief notice of the species of true Mus.

In regard to the first it is noteworthy that house-mice isolated on a small sandbank near Dublin have developed a special colouring of their own; also that distinct local varieties, Mus musculus murinus and Mus musculus fœrobënsis, inhabit respectively St Kilda and the Faeroes. In Central Asia there exists a wild mouse (Mus bactrianus), and likewise a second species (Mus vagnæri), with the habits of a house-mouse, both of which are closely allied to Mus musculus; while there is a third kind (Mus gerbillus), also nearly related, in the deserts of North Africa. According to Major G. E. H. Barrett-Hamilton it is probable that Mus bactrianus and Mus musculus are respectively desert and house modifications descended from some Central Asian ancestor more or less nearly allied to Mus vagnæri. As regards the other two British species, it must suffice to say that they are local races of each. Mus sylvaticus being represented by several in the British Isles, although there is but one British representative of Mus minutus. It may be added that by some naturalists both Mus sylvaticus and Mus minutus are separated from Mus as Micromys.

MOUSE-BIRD (Du. Muisvogel), the name by which in Cape Colony and Natal the members of the genus Colius of M. J. Brisson are known—probably from their singular habit of creeping along the boughs of trees with the whole tarsus applied to the branch. By the earlier systematists, Colius was placed among the Fringillidae; but the investigations of J. Murie and A. H. Garrod on its internal structure showed that it was not a true Passerine, and it is now placed in a separate family, Coliidae, amongst Coraciiform birds, near the trogons and swifts (q.v.). The Coliidae are small birds, with a rather finch-like bill, a more or less crested head, a very long tail, and generally of a dun or slate-coloured plumage that sometimes brightens into blue or is pleasingly diversified with white or chestnut. They feed almost wholly on fruits, but occasionally take insects, in quest of which they pass in bands of fifteen or twenty from tree to tree. Seven species are believed to exist, all belonging to the Ethiopian region (of which the Family is one of the most characteristic), and ranging from Abyssinia southwards. Three species inhabit Cape Colony. (A. N.)

MOSSORGSKY, MODESTE PETROVICH (1835-1881), Russian composer, was born at Karevo, government of Pskov, in March 1835, and entered the army at an early age. He came of a musical family, and was himself a talented amateur, and an acquaintance with Balakirev and Dargomysky led him to more serious study of composition, so that in 1857 he left the army and devoted himself to music, though this step entailed his earning his living as a government clerk and a prolonged period of poverty. His greatest opera, Boris Godounov, based on Pushkin’s drama, was produced in St. Petersburg in 1874, and on it his reputation stands as one of the finest creative composers in the ranks of the modern Russian school. He also wrote a number of songs and orchestral works of a realistic national type. In later life he suffered much from ill-health, and died in St. Petersburg on the 16th (28th) of March 1881.

MOUSTACHE, or MUSTACHIO, the hair worn unshaven on the upper lip (see BEARD). The spelling “moustache,” now the most common in English usage, is the French form of Ital. mustachio, an adaptation of a Doric dialectical μοστάχιο, upper lip, also hair on the lip; this is generally taken to be a variant of μοσταχία, jaws, mouth, connected with μόσταχος, to chew; cf. “mastic,” chewing-gum, and “masticate,” to chew.

MOUSTRIAN, the name given by the French anthropologist G. de Mortillet to the second epoch of the Quaternary Age, and to the earliest in his system of cave-chronology. It is so named from a cave (Le Mouster), on the right bank of the Vézère, an affluent of the Dordogne, above Les Eyzies and Tayac, which has yielded typical palaeolithic implements. The epoch was characterized by cold wet climate, by the supposed existence of Man of the Olom type, that is, nearly as dolichocephalous as the Neanderthal type, but with supervalvular ridges flat, and frontal bones high, and by the occurrence of the musk-ox, the horse, the cave-bear, Rhinoceros tichorhinus and the mammoth. The typical implements are flint points or spear-heads, left smooth and flat on one side, as struck from the cave, pointed and edged from the other side; a scraper treated in the same way, but with edge rather upon the side than at the end, as in the succeeding Solutrian and Madeleiniæ epochs. Relics of the Mousterian age have been also found in Belgium, southern Germany, Bohemia and southern England, some of the “finds” including human remains.

MOUTH AND SALIVARY GLANDS. The mouth (A.S. mdus), in anatomy, is an oval cavity at the beginning of the alimentary canal in which the food is masticated. The opening is situated between the lips, and at rest its width reaches to the first premolar tooth on each side.

The lips (A.S. lippa) are fleshy folds, surrounding the opening of the mouth, and are formed, from without inward, by skin, superficial fascia, orbicularis oris muscle, submucous tissue, containing numerous labial glands about the size of a small pea, and mucous membrane. In the deeper part of each lip lies the coronary artery, while in the mid-line is a reflection of the mucous membrane on to the gum forming the frenum labii.

The cheeks (A.S. clæce) form the sides of the mouth and are continuous with the lips, with which their structure is almost identical save that the buccinator muscle replaces the orbicularis oris and the buccal glands the labial. In the subcutaneous fascia is a distinct mass of fat, specially large in the infant, which is known as the sucking pad. On the buccal surface of the cheek, opposite the second upper molar tooth, is the papilla which marks the opening of the parotid duct, while, just behind, are four or five molar glands, larger than the buccal, the ducts of which open opposite the last molar tooth. The mucous membrane of the cheek, like that of the rest of the mouth, is of the stratified squamous variety (see EPITHELIAL TISSUES) and is reflected on to the gums.

The gums (A.S. gumma) consist of mucous membrane connected by thick fibrous tissue to the periosteum of the jaws. Round the base of the crown of each tooth the membrane rises up into a little collar.

The vestibule of the mouth is the space between the lips and cheeks superically and the gums and teeth deeply. It communicates with the true cavity of the mouth by the clefts between the teeth and by the space behind the last molar teeth.

The roof of the mouth is concave transversely and antero-posteriorly, and is formed by the hard and soft palate. The hard palate consists of mucous membrane continuous with that of the gums and bound to the periosteum of the palate processes of the maxillæ and palate bones by firm fibrous tissue. In the mid-line is a slight ridge, the palatine raphe, which ends in front in a little eminence called the palatine papilla, marking the position of the anterior palatine canal. From the anterior part of the raphe five or six transverse ridges or rugae of the mucous membrane run outward. (For a description of the soft palate see Pharynx.)

The floor of the mouth can only be seen when the tongue is raised, then the reflection of the mucous membrane from the gums to it is exposed. In the mid-line is a prominent fold called the frenum linguae, and on each side of this a sublingual papilla, on to the summit of which the duct of the submaxillare gland opens. Running outward and backward from this is a ridge called the plica sublingualis, which marks the upper edge of the sublingual gland, and on to which most of the ducts of that gland open. (For a description of the Tongue and the Teeth see special articles on those structures.)

The salivary glands are the parotid, submaxillary and sublingual, though the small scattered glands such as the labial, buccal, molar, lingual, &c., probably have a similar function.

The parotid gland (Gr. ραιδή beside, όεαρ), is the largest of these glands, and is situated between the ear and the ramus of the mandible. In a transverse section through the head the level of
the mouth the gland looks more or less triangular, its outer wall or base being bounded by the parotid fascia, its anterior by the jaw, and its posterior by the mastoid process and sternomastoid muscle. Why the anterior and posterior walls meet to form the apex is the styloids process. Above the gland reaches to the zygoma, and to the level of the angle of the jaw, where a strong process of the deep cervical fascia, called the stylo-mandibular ligament, separates it from the submaxillary gland; indeed the parotid is often described as lying in a bag formed by deep cervical fascia. This is the outline of the gland is obscured by several processes, one of which, the facial lobe, runs forward, superficial to the masseter muscle, accompanying the duct. A separate part of this is the subcutaneous parotid; another known as the pterygoid lobe, passes forward, deep to the ramus of the jaw, to the space between the two pterygoid muscles. A third wraps round the front of the styloid process and may be flattened surface rests against the sublingual fossa in the lower jaw, while the inner one is in contact with the genio-hyoglossus muscle, the submaxillary duct and the lingual nerve. Its upper edge forms the sublingual fold (plica sublingualis) in the mucous membrane. The submandibular gland is large, pyramidal, and numerous, open; these are sometimes called the ducts of Rivinius, but the term "sublingual ducts" is simpler and more expressive. Occasionally an anterior sublingual duct (duct of Bartholin) opens with or into the submaxillary duct.

Embryology.
The fore-gut (see Alimentary Canal) at firsts blindly, ventral to the region of the hind brain, while in front of it is the overhanging fore-brain. When the heart develops, ventral to the fore-gut, the cleft of the fore-gut also opens ventrally to form a transverse cleft, without any lateral boundaries and lined by ectoderm, is left between these two structures. This is the stomato- daeum or primitive mouth, the ectoderm of which rests against the endoderm of the fore-gut to form the bucco-pharyngeal membrane, and so separates the two chambers. The position of this membrane does not correspond to the fauces or hinder limits of the adult mouth, but is much more oblique, so that the front part of the roof of the pharynx is formed by stomato-daenum while the greater part of the floor of the permanent mouth is fore-gut. During the third week the membrane disappears, and it is probable that to its early atrophy is due the fact that no traces of it can be seen in the adult. Growing down from the region of the fore-brain is the fronto-nasal process, which forms the nose and the middle piece of the upper lip, while the lateral parts of the mouth are closed in by two processes, on each side of which the lower or mandibular processes (considerably more develop) form the jaw. The upper jaw and lip, thus separating the heart from the mouth cavity. The upper or maxillary process grows inward more slowly, but at last joins with the fronto-nasal process, and in the adult the lines of fusion may be seen on the cleft, called the ridge of skin which runs down from the nostril to the margin of the lip, and enclose that slightly depressed vertical gutter to which the term philtrum is given. Besides forming the philtrum the fronto-nasal process is responsible for the form of roof of the mouth which is formed of the premaxillary bones, an area marked out by lines drawn on each side from between the lateral incisor and canine teeth to the palate papilla. At the cavity of the mouth and nose are one, but they anastomose which is the palatine processes, like shelves from the maxillary processes and meet in the mid-line. The maxillary and sublingual salivary glands develop as small outgrowths of the bucal epithelium which are canalized later, while the tonsils and adenoids develop as outgrowths of the gut.
custom now to have the patient lying upon his back, with the head hanging over the end of the table, so that the blood may sink. After the cutting process, the mouth is washed with water and with a small piece of cotton by the nostrils, instead of running the risk of finding its way into the windpipe and lungs. (See Cleft Palate."

**Mumps.**—Inflammation of the parotid gland is apt to occur as an epidemic, children being chiefly attacked. The disease, which is highly infectious, is called mumps, and is associated with much swelling below and in front of the ear, or ears. There is stiffness of the jaw and there is a difficulty in swallowing. There is slight local tenderness, and the temperature may, perhaps, run up a degree or two. For the sake of others, the child should be kept away from school for three or four weeks.

**Salivary Calculus.**—Sometimes a deposit of phosphate and carbonate of lime slowly takes place from the saliva, and gives rise to the formation of a small concretion in the duct of one of the salivary glands. When the concretion blocks the duct, so that the saliva is unable to find its way into the mouth, a fluid swelling forms behind the blockage, giving rise to inconvenience and unsightliness. The swelling is at its greatest during a meal, when the secretion of the saliva is necessarily rapid; subsequently it disappears, recurring, however, at the next meal-time. In many cases the patient is conscious of the fact of there being a hard, movable "kernel," the size, perhaps, of a barleycorn, a cherry-stone or even of a small almond, in the course of the duct. In the removal of the calculus every endeavour should be made to effect its escape into the mouth, as, if the skin were incised for its extraction, the wound might refuse to heal, a salivary fistula resulting. (E. O."

**MOUTHPIECE** (Fr. embouchure; Ger. Mundstück; Ital. bocchino), in music, that part of a wind instrument into which the performer directs his breath in order to induce the regular series of vibrations to which musical sounds are due. The mouthpiece is either taken into the mouth or held to the lips; by an extension of the meaning of the word, mouthpiece is also applied to the corresponding part of an organ-pipe through which the compressed wind is blown, and containing the sharp edge known as "lip," or the reed necessary for the production of sound. The quality of a musical tone is due primarily to the form or method of vibration by means of which sound-waves of a distinctive character are generated, each consisting of a pulse or half-wave of compression and of a pulse of rarefaction; the variety in the quality of tone, or "timbre," obtainable in various wind instruments is in a great measure due to the form and construction of the mouthpiece, taken in combination with the form of the column of air within the tube and consequently of the bore of the latter. The principal functions of the mouthpiece are (1) to facilitate the production of the natural harmonic scale of the instrument; (2) to assist in correcting errors in pitch as the ear directs; (3) to enable the performer to obtain the dynamic variations whereby he translates his emotional interpretation of the music into sound. Mouthpieces, therefore, serve as a means of classifying wind instruments. They fall into the following groups:

1. The **syrinx or pan-pipe mouthpiece** consists merely of the open end of the tube across (not into) which the player directs his breath in a current which impinges obliquely against the sharp edge of the pipe, producing the series of shocks or pulses required in the air stream from his lips; this in turn, when in a state of vibration, serves to generate the sound-waves within the pipe. This principle was embodied in the **nay**, or long oblique flute of the ancient Egyptians, which was probably the first mouthpiece discovered and put into practical use by prehistoric man. A modification of this principle has been applied to the transverse flute (q.v.), in which the air stream or exciting current is directed across a lateral hole in the head joint of the instrument.

2. The **whistle mouthpiece** is based on that of the flute with this modification, that the air current, instead of being compressed by the lips of the performer and then directed through ambient air to break against the sharp edge of the lateral hole, is compressed mechanically in passing through a narrow channel so constructed within the mouthpiece that the stream of air impinges with force against the sharp edge of a lip cut into the pipe below the channel. The principal of the whistle mouthpiece has been applied with slight modifications to a variety of instruments such as the recorder (q.v.) family in England (Fr. flûte à bec, flûte douce, flûte angloise; Ger. Schnabelflöte, Plockflöte; Ital. flauto dolce, in which the channel assumes the form of a beak, the flagolet (q.v.), the penny whistle, &c. All these whistle or fipple pipes have at all times enjoyed great popularity owing to the ease with which they can be played."

The flute or fipple-work of an organ is the result of the adaptation of the same principle to both open and stopped pipes (fig. 1). Compressed air is fed in at an even pressure through the foot AB, and passing through the slit or channel EC, impinges with force against the lip D, producing the requisite series of pulsations in the pipe FF. By this elimination of the human element in the organ, all possibility of communicating the emotion of the performer becomes impossible. With a rigid mouthpiece any increase in wind pressure would affect the pitch, causing the note to become unsteady or to jump to the harmonics; the result could in no case be a crescendo.

3. **Reed Mouthpieces.**—There are three kinds of reed mouthpieces: the double, the single or beating, and the free reed. The function of the reed, a term originally applied to a part of the stalk of the Arundo donax or satura, but now extended to any vibrating tongue of wood or metal, is to break up an existing current of air, otherwise flowing in an uninterrupted even stream, into regular beats or pulses, corresponding with the beats or vibrations of the reed. Reeds proper or wooden vibrators being flexible, are compelled to vibrate synchronously with the column of air within the tube and to accommodate their frequency of vibration to the length of the tube as it varies according to the lateral holes which remain open."

A. **The double reed** is the most primitive and probably the oldest of the reed mouthpieces; it was used by the ancient Egyptians. A straw flattened at one end and inserted into a pipe having at the mouthpiece end the same diameter as the straw contains all the rudimentary features of the double-reed mouthpiece common to the members of the oboe family, i.e. a reed, a bore, and contra-fagotto, to the bassoon, and to the chainer of the bagpipe. The earliest Greek aulos (q.v.) was probably played by means of a double reed, since the mouthpiece was known as **syrinx**, signifying a pair of like things. The oboe or *flûte à bec* (fig. 2) is made from two pieces of reed stalk, flattened and thinned at the end and bound together with waxed thread, thus forming a tube with a constriction in the middle, above which the section is oval and below circular. A double-reed wind instrument may be enclosed in an air-chamber or reservoir, as in the 16th-century cromorne (q.v.), in the chainer of the bagpipe (q.v.), in the reeds of organ-pipes and in certain instruments popular in France during the 17th century known as **bois de Pau**, in all of which the air-chamber is supplied with compressed air by the mouth of the performer, whose lips do not come into contact with the reed, a method which makes the production of harmonics impossible, and thus restricts the natural range of the instrument to one of over-floowing, i.e. the production of harmonics by increased pressure of breath accompanied by a proportional tension of the lips, became known, the air-chamber

---

3. See also excavations in Egypt were found to contain two pipes, and in addition five pieces of reed without bore or holes, and three pieces of straw suitable for making double-reed mouthpieces. See Victor Loret, "Les Flûtes égyptiennes antiques," *Journal asiatique* (Paris, 1889), [8].
of the oboe was discarded and the reed taken directly into the mouth. It is certain that the ancient Greeks obtained the full compass of the aulos by overblowing, since the process by which a modern performer on the oboe breathes into the vertical aperture, or reed, harmonics is described by Aristotle and others.

The vibrating length of the reed is controlled by taking the latter more or less deeply into the mouth and by varying the tension of the reed either by beating upon it; the shorter the free end the higher the pitch of the note or harmonic obtained. The action of the lips on the reed is isentropic in extent by a tuning-wire, with the difference that the lips being mobile, different notes can be obtained from the same pipe, whereas in the organ each voice is adapted to its own pipe and gives one note only.

B. The beating- or single-reed mouthpiece, also known as the clarinet mouthpiece, is likewise of flint antiguity; the principle is the same as that of the modern Egyptian argouh (q.v.), which has been traced once at least in the hieroglyphics and in a fresco from the tombs at Saqqara. The mouthpiece of the argouh is the primitive form of beating-reed most regularly in popular districts as a "squeaker." A lateral slit is made in a piece of reed and a little tongue is detached from the slit towards the knuckle of the reed, which is pressed close and open the aperture at regular intervals, and the exciting agent here acts by means of a series of concussions. The metal vibrators of the oblong shapes of metal are joined by the tongue is a separate piece of metal fixed by means of nuts over an aperture, the vibrating length being regulated by means of a clarinet mouthpiece (fig. 2) has the advantage of being capable of being moved and the point bevelled and thinned at the edge to correspond with the end of the reed, shaped like a spatula. The underpart of the mouthpiece is flatter to order to form a table for the support of the reed, which is adjusted thereon with great nicety by means of a ligature or metal band fastened by screws, the longitudinal aperture 1 in long and 3½ in. wide, communicating with the bore, is cut in the table and covered by the reed, so that the only opening is at the point, where for the distance of 1½ in. the reed is thinned and the table curves backwards, leaving a gap of about 1 mm. between itself and the reed-tongue (for the Bb clarinet). The curve of the table and dimensions of the gap are therefore of considerable importance. The reed is set in vibration by the breath of the performer, and being flexible it beats against the table, alternately opening and closing the gap, and producing, as already mentioned above, a series of concussions in harmony with the vibrations of the air-column within the tube, according to the length determined by the opening of the lateral holes and keys.

C. The free-reed, illustrated under Free Reed Vibrator, is similar in construction to the beating-reed, but the metal vibrator is cut slightly smaller than the aperture through which wind is forced freely, alternately opening and closing it without concussion and with complete elasticity. The main difference in practice between these two outwardly similar reeds is a very important one. The reed being free and there is no siphon of wind therefore produces not an harmonic overtone but a crescendo. The principal use of the free-reed is in the harmonium (q.v.) and in the reed-work of organs on the continent of Europe. In English organs the beating-reeds is almost exclusively used, but further used in the Chinese cheng (q.v.), through which it became known in Europe in the 18th century, and in the accordion, concertina and mouth-organ, under which headings its acoustic properties are more fully discussed in reed organ-pipes of 18th century.

4. Cup-Mouthpieces.—Brass wind instruments are played by means of cup or funnel-shaped mouthpieces, generally made of silver. The principal feature of the cup is the shape of the aperture in the bottom, where it communicates with the bore of the tube (known as the "gruit" or "throat"), and its distance from the bottom. The shallower the cup the more suitable it is for producing the higher harmonics. The lips of the performer rest lightly but firmly against the rim of the mouthpiece, vibrating like double reeds from the force of the breath and communicating these vibrations in the form of pulses to the breath as it issues from them in a stream. This stream or exciting current passes into the cup ready to generate sound-waves in the air column contained within the main tube. If, as in the trumpet and in a lesser degree in the trombone, the curve of the bottom of the cup terminates at the hole in an abrupt angle, the quality of the tone developed is brilliant and blaring, being broken up by the sharp edge of the throat. In the horn, which has a funnel-shaped mouthpiece, the timbre is in complete contrast when the instrument is properly played, being elastic, sonorous and very mellow, qualities which may be attributed to the absence of angle or bottom to the cup, the sides gradually sloping and converging insensibly into the bore of the tube.

MOVERS, FRANZ KARL (1806-1866). German Roman Catholic divine and Orientalist, was born at Kesselfeld in Westphalia, on the 17th of July 1806. He studied in Munich and Oriental languages at Münster, was parish priest at Bermen near Bonn from 1833 to 1839, and professor of Old Testament theology in the Catholic faculty at Breslau from 1839 to his death on the 28th of September 1856. His elaborate works, Die Phönisiere (1841-1850) and Phönizische Texte, erklärt (1845-1847), attained a high reputation. Of his other writings two biblical studies were of some importance, his Kritische Untersuchungen über die alttestamentliche Chronik (1834), and his Latin essay on the two recensions of the text of Jeremiah, De urinsequae recensionis voticitorum Jeremiae...indole et origine (1837).

MOW. (1) To cut down standing hay or corn with a scythe or machine drawn by a horse or mechanical power (see Reaper). The word in O.Eng. is mowan, a verb common to the West German languages, cf. Du. maaien, Ger. mähen; the root is also seen in "meadow," Gr. μεδος and Lat. meares, to reap, cut, cf. messis, harvest. (2) A stack or rick of hay, and sometimes also of beans, peas or other crops. The word in O.Eng. is mäga, mäka, and is cognate with Swedish and Norwegian muga, heap, cf. Swedish alimgage, crowd of people, Danish almuc. "Mow" is chiefly dialectal in England, where it is a common name, e.g. the Barley Mow, on the sign-boards of country inns. From these two words must be distinguished (3) "mow," a gime, now obsolete or purely literary, and generally found in combination with "mop," cf. "mopping and mowing" in King Lear, iv. 1. 64. This is the same word as the modern Fr. mousse, pout, which is of obscure origin.

MOBAT, SIR OLIVER (1820-1903). Canadian judge and statesman (Q.C. 1836, LL.D. 1872, K.C.M.G. 1892, G.C.M.G. 1897). He was the son of John Mowat, who fought in the Peninsular War and was Sir Arthur Wellesley's (afterwards duke of Wellington). Born at Kingston, Ontario, on the 22nd of July, 1820, he was educated by private tuition and in 1836 began the study of law under Mr. (afterwards the Rt. Hon. Sir John A. Macdonald. Called to the bar in 1841, he soon became a leading Chancery counsel and in 1856 "took silk." He entered parliament in 1858 as a Liberal and in 1861 became postmaster-general. He took a prominent part in the proceedings of the Quebec Conference of 1864, which settled the terms of the Confederation of the British North American provinces, and in the same year was appointed vice-chancellor of Upper Canada. Eight years afterwards (1872) the Hon. Edward Blake resigned the premiership of the province of Ontario, and Mowat was called to fill the vacant post. He continued to be premier of Ontario until the 13th of July 1896. Assisted by able colleagues and holding always a strong majority in the house, he gave to Ontario a
body of laws many of which have been copied by other provinces of the dominion and by several states of the American Union. In eight important cases which he argued before the Judicial Committee of H.M. Privy Council, he established, as against the contention of Sir John A. Macdonald, the proposition that the provincial legislatures were co-ordinate with and not subordinate to the parliament of Canada. To weaken his influence the Conservatives at Ottawa attempted to extend the boundaries of Manitoba, thereby reducing the area of Ontario; but Mr Mowat again appealed to the Judicial Committee and was again successful. According to Sir John A. Macdonald, Ontario contained under the “Quebec Act” only 116,782 sq. m.; but Mr Mowat gave it an area of 266,862 sq. m. When he returned home after this great victory he received an ovation unparalleled in the history of any Canadian statesman. One of his prominent characteristics was his loyalty to Britain. Between 1886 and 1896 Canadian trade was depressed, and men were leaving the country in thousands for the United States. Dr Goldwin Smith and other prominent men advocated commercial union with the United States, viz. that the two countries should maintain a uniform tariff against the rest of the world, with free trade as between themselves. Sir Oliver Mowat saw in this “veiled annexion,” and by letters, speeches and pamphlets he crushed the movement so completely as to make his party more imperialist than the Conservatives had ever been. In July 1896 he was called to the senate of Canada and made minister of justice. In November 1897 he was appointed lieutenant-governor of his native province, and this office he held until he died at Government House, Toronto, on the 19th of April 1903.

See C. R. W. Biggar, Sir Oliver Mowat, a Biographical Sketch (Toronto, 1905).

(C. R. W. B.)

MOWBRAY, the name of an Anglo-Norman baronial house, derived from Montbray (Manche) in Normandy south of St Lo. It was founded at the Conquest by Geoffrey (de Montbray), bishop of Coutances. His brother's son Robert, who rebelled with him against William Rufus on the Conqueror's death, was made, after their reconciliation, earl of Northumberland, as his uncle's heir but was forfeited and imprisoned for life on rebelling again in 1095. A sister of Bishop Geoffrey was mother by Roger d'Aubigny (of Aubigny in the Cotentin) of two sons, Nigel and William, who were ardent supporters of Henry I., and were rewarded by him with great estates in England. William was made king's butler, and was father of William d'Aubigny ("de Albin"), first earl of Arundel (see ARUNDEL); Nigel was rewarded with the escheated fief of Geoffreys de la Guerce, of which Melton (Mowbray) was the head, and with forfeited lands in Yorkshire. Nigel married, by dispensation, the wife of his cousin, the imprisoned earl, but afterwards divorced her, and by another wife was father of a son Roger, who took the name of Mowbray.

Roger, a great lord with a hundred knights' fees, was captured with King Stephen at the battle of Lincoln, joined the rebellion against him (1135), founded abbey, and went on crusade. His grandson William, leader in the rise against King John, was one of the 25 barons of the Great Charter, as was his brother Roger, and was captured fighting against Henry III. at the rout of Lincoln (1217). His grandson Roger (1296–1298), who was summoned to parliament by Edward I., was father of John (1286–1322), a warrior and warden of the Scottish March, who, joining in Thomas of Lancaster's revolt, was captured at Boroughbridge and hanged. His wife, a Braose heiress, added Gower in South Wales and the Bramber lordship in Sussex to the great possessions of his house. Their son John (d. 1361) was father, by a daughter of Henry earl of Lancaster, of John, Lord Mowbray (c. 1328–1368), whose fortunate alliance with the heiress of Lord Segrave, by the heiress of Edward I.'s son Thomas, earl of Norfolk and marshal of England, crowned the fortunes of his race. In addition to a vast accession to their lands, the earldom of Nottingham and the marshalship of England were bestowed on them by Richard II., and the dukedom of Norfolk followed (see NORFOLK, THOMAS MOWBRAY, 1st duke of).

The 1st duke left two sons, of whom Thomas the elder was only recognized as earl marshal. Beheaded for joining in Scrope's enserfacy against Henry IV. (1400), he was succeeded by his brother John, who was restored to the dukedom of Norfolk in 1424. His son John, the third duke, was father of John, 4th and last duke, who was created earl of Warrenne and Surrey in his father's lifetime (1451). At his death (1475) his vast inheritance devolved on his only child Anne, who was married as an infant to Edward IV.'s younger son Richard (created duke of Norfolk and earl of Nottingham and Warrenne), but died in 1481.

The next heirs of the Mowbrays were then the Howards and the Berkeleys, representing the two daughters of the first duke. Between them were divided the estates of the house, the Mowbray dukedom of Norfolk and earldom of Surrey being also revived for the Howards (1483), and the earldom of Nottingham (1483) and earl marshalship (1485) for the Berkeleys. Both families assumed the baronies of Mowbray and Segrave, but Henry Howard was summoned in his father's lifetime (1460) as Lord Mowbray, which was deemed a recognition of the Howards' right in the barony. In 1515, when the Lords Segrave and the Lords Petre, and in 1787 Lord Stourton was summoned as Lord Mowbray and Segrave. The former dignity is claimed as the premier barony, though De Ros ranks before it. Lord Stourton's son claimed, but unsuccessfully, in 1901–1906 the earldom of Norfolk (1312), also through the Mowbrays. Of the Mowbray estates the castle and lordship of Bramber is still vested in the dukedom of Norfolk. The heraldic badge of the house was a mulberry-tree.

MOWBRAY, HARRY SIDDONS (1878– ), American artist, was born of English parents at Alexandria, Egypt, on the 5th of August 1858. Left an orphan, he was taken to America by an uncle, who settled at North Adams, Mass. After a year at the United States Military Academy at West Point, he went to Paris and entered the atelier of Léon Bonnat, his first picture, "Aladdin," bringing him to public notice. He was made a full member of the National Academy of Design in 1891. Subsequently he was best known for his decorative work, especially "The Transmission of the Law," Appellate Court House; ceiling for the residence of F. W. Vanderbilt; and the ceiling and walls of the library of the University Club—all in New York. This last was executed in Rome, where, in 1903, he was made director of the American Academy.

MOWBRAY, ROBERT (d. 1175), a Norman who was appointed earl of Northumberland between 1080 and 1082. In 1088 he and his uncle Geoffrey, bishop of Coutances, sided with Robert, duke of Normandy, against William Rufus, but they were pardoned at the close of the rebellion. In 1091 Mowbray defeated Malcolm Canmore of Scotland, who had invaded England, and in 1093 surprised and slew this king near Alnwick; soon after this event he succeeded to his uncle's vast estates. In 1095 he led a rebellion which had for its object the transference of the crown from the sons of the Conqueror to Stephen of Aumale. Rufus marched against the earl in person, and Mowbray shut himself up in Bamborough Castle, but he was captured and brought to London; the earl was escaped, and was captured again. He was then deprived of his possessions and kept a prisoner for the rest of his life, nearly thirty years.

MOXON, EDWARD (1801–1858), British poet and publisher, was born at Wakefield in 1801. In 1826 he published a volume of verse, entitled The Prospect, and other Poems, which was received with some favour. In 1830 Moxon was started by Samuel Rogers as a London publisher in New Bond Street. The first volume he issued was Charles Lamb's Album Verses. Removing to Dover Street, Piccadilly, Moxon published an illustrated edition of Rogers's Italy, £10,000 being spent upon the illustrations. Wordsworth entrusted him with the publication of his works from 1835 onwards, and in 1839 he issued the first complete edition of Shelley's poems. Some passages in Queen Mab were the cause of a charge of blasphemy being
made against Moxon in 1841. The case was tried before Lord Denman, and Sergeant Talfourd defended Moxon, but the jury returned a verdict of guilty, and the offensive passages were for a time eliminated. In 1840 he published Browning's Sordello; and in succeeding years works by Lord Houghton, Tom Hood, Barry Cornwall, Lord Lytton, Browning and Tennyson appeared. Edward Moxon died on the 3rd of June 1858, his business being continued by Mr J. B. Payne and Mr Arthur Moxon, who in 1865 published Swithinburne's Aitlania in Calydon; but in 1871 it was taken over by Mesars Ward, Lock & Tyler.

Moxos, Moxos, Moxos, a tribe of South American Indians living around the head-waters of the Madeira river, northern Bolivia, particularly on both banks of the Mamoré. They submitted to Inca domination, but in 1564 gallantly repulsed the Spaniards. A century later, however, the Jesuits were welcomed, and the Moxos became devout Catholics. They number some 30,000.

Mozambique [São Sebastião de Moçambique], a town of Portuguese East Africa, seat of a Roman Catholic bishopric in the province of Goã, in 15° 4' S., 40° 44' E. The town occupies the whole of a small coral island at the mouth of Mozoril Bay. The name Mozambique, used first to designate the island, was also given to the town and extended to the whole of the Portuguese possessions on the east coast of Africa. There are three forts, of which the principal, St Sebastian, at the northern extremity of the island was built in 1510 entirely of stone brought from Portugal. It is quadrangular, and has bastioned walls nearly 70 ft. high. In it are mounted some modern guns. The harbour is small, but deep enough to admit vessels drawing 25 feet.

The inhabitants, who number about 7000, consist chiefly of Mahomedian negroes of mixed descent speaking a dialect of the Makwa language. There are Parsee, Banyan, Goanese and Arab traders, and about 300 Europeans, besides half-caste Portuguese. The annual average value of the imports for the three years 1904-1906 was £97,035, of the exports £71,636. The import trade is chiefly with Great Britain and India; the articles in chief demand being cotton, coloured shawls and hardware. The exports are chiefly groundnuts, rubber of inferior quality, sesame and other oil seeds, tortoise-shell and ebony. Germany has a large share of the exports.

Mozambique was discovered by Vasco da Gama in 1498. There was then a flourishing Arab town on the island, of which no trace exists. The history of the Portuguese town is closely identified with that of the province, for which see PORTUGUESE EAST AFRICA. The commercial and political importance of Mozambique has been eclipsed by Lourenço Marques.

Mozarab [Spanish Mozarabe, a corruption of the Arabic Mūṣārīb, coll. Mūṣārība], a general term for persons not Arab by race who have assimilated themselves to the Arabs. It was applied by the Moslems in Spain to the Christian communities existing among them, in Cordova, Seville, Toledo and other large cities, in the exercise of their own laws and religion. The ancient liturgy used by the Christians of Toledo is commonly known as Mozarabic.

Mozart, Wolfgang Amadeus I (1756-1791), German composer, was born at Salzburg on the 27th of January 1756. He was educated by his father, Leopold Mozart, a violinist of high reputation in the service of the archbishop of Salzburg. When only three years old he heard the harpsichord lessons of his sister Maria, five years his senior. A year later he played minuets, and composed little pieces, some of which are still preserved in Maria's music-book. When five years old he performed in public for the first time, in the hall of the university. In 1762 Leopold Mozart took Wolfgang and Maria on a musical tour, during the course of which they played before most of the sovereigns of Germany. The little "Wolferl's" charming appearance and disposition endeared him to every one; and so ingrained and natural were his manners that at Vienna he sprang upon the empress's lap and kissed her. The emperor Francis I sat by his side while he played, and called him his "little magician." When he slipped one day on the polished floor the archduchess Marie Antoinette, afterwards queen of France, lifted him up, whereupon he said: "You are very kind; when I grow up I will marry you." Yet, in spite of the petting he received at court, he remained as gentle and docile as ever, and so amenable to parental authority that he used to say, "Next after God comes my father." In 1763 the whole family started again. Wolferl now sang, composed, and played on the harpsichord, the organ and the violin, winning golden opinions everywhere. At every court he visited he was loaded with caresses and presents; but the journeys were expensive, and the family terribly poor. In Paris they lodged at the Bavarian embassy, giving performances on a grand scale both there and at Versailles, where Wolferl's organ-playing was even more admired than his performance on the harpsichord. Here, also, he published his first compositions—two sets of sonatas for the harpsichord and violin.

On the 10th of April 1764 Leopold Mozart brought his family to England, engaging a lodging in Cecil Street, St Martin's Lane, whence he afterwards removed to Frith Street, Soho. On the 27th of April and the 10th of May Wolferl played before the royal family with immense success, accompanying the queen in a song and playing at sight anything that the king set before him. He now made his first attempt at the composition of a symphony; published a third set of sonatas, dedicated to the queen; and wrote an anthem for four voices entitled God is our Refuge, for presentation to the British Museum. On the 17th of September 1765 the family left England for the Hague, where they remained some time, and where in March 1766 the young composer made his first attempt at an oratorio, commanding in Holland a success as great as that he had already attained in London, and astonishing his hearers at Haarlem by performing in April some of the larger works at the Hague. In September 1767 he paid a second visit to Vienna, and at the suggestion of the emperor Joseph II. composed an opera buffa, La Finta semplice, which, though acknowledged by the company for which it was written to be "an incomparable work," was suppressed by a miserably cabal. The archbishop of Salzburg hearing of this commanded a representation of the rejected work in his palace, and appointed the young composer his "maestro di capella." The office, however, was merely an honorary one, and, since it did not involve compulsory residence, Leopold Mozart determined to complete his son's education in Italy, to which country he himself accompanied him in December 1769.

Wolfgang, now nearly fourteen years old, was already an accomplished musician, needing experience rather than instruction, and gaining it every day. At Milan he received a commission to write an opera for the following Christmas. Arriving in Rome on the Wednesday in Holy Week, he went at once to the Sistine Chapel to hear the celebrated Miserere of Gregorio Allegri, which, on returning to his hotel, he wrote down from memory note for note—a feat which created immense sensation, for at that time the singers were forbidden to transcribe the music on pain of excommunication. Returning to Rome towards the end of June, he was invested by the pope with the order of "The Golden Spur," of which he was made a cavalieri, an honour which he prized the more highly because, not many years before, it had been conferred upon Gluck. In July he paid a second visit to Bologna, when the Accademia Filarmonica, after subjecting him to a severe examination, admitted him to the rank of "compositor," notwithstanding a statute restricting this preference to candidates of at least twenty years old. The exercise which gained him this distinction is a four-part composition (Kochel's Catalogue, No. 86) in strict counterpoint on the antiphon "Miserere praemium," written in the severe ecclesiastical style of the 16th century and abounding in points of ingenious imitation and device.

1 In the baptismal register his name stands, Joannes Chrysostomus Wolfgangus Theophilus (Lat. Amadeus, Ger. Gottlieb).
2 The German diminutive of Wolfgang.
3 The original autograph is numbered "Select Case C, 27. d."
4 Virtue militiae equus.
In October 1770 Wolfgang and his father returned to Milan for the completion and production of the new opera. The libretto, entitled Mirabile, Re di Ponto, was furnished by an obscure poet from Turin, to the great disappointment of the young maestro, who had hoped to set a drama by Metastasio. The progress of the work was interrupted from time to time by the miserable intrigues which seem inseparable from the lyric stage, exacerbated in this particular case by the jealousy of the resident professors, who refused to believe either that an Italian opera could be written by a native of Germany, or that a boy of fourteen could manage the orchestra of La Scala, at that time the largest in Europe. Fortunately the detractors were effectively silenced at the first full rehearsal; and on the 26th of December Wolfgang took his seat at the harpsichord and directed his work amidst a storm of genuine applause. The success of the piece was unprecedented. It had a continuous run of twenty nights, and delighted even the most captious critics.

Wolfgang's triumph was now complete. After playing with his usual success in Turin, Verona, Venice, Padua and other Italian cities, he returned with his father to Salzburg in March 1771, commissioned to compose a grand dramatic serenade for the approaching marriage of the archduke Ferdinand, and an opera for La Scala, to be performed during the season of 1773. The wedding took place at Milan on the 21st of October; and the serenade, Ascendio in Alba, was produced with an effect which completely eclipsed the new opera of Hasse, Ruggiero, composed for the same festivity. Hasse generously uttered the oft-quoted prophecy, "This boy will cause us all to be forgotten."

During the absence of Wolfgang and his father the good archbishop of Salzburg died; and in the spring of the year 1772 Hieronymus, count of Colloredo, was elected in his stead, to the horror of all who were acquainted with his real character. The Mozart family did their best to propitiate their new lord, for whose installation Wolfgang, after his return from Milan, composed an opera, Il Sogno di Scipione; but the newly-elected prelate had no taste for art, and was utterly incapable of appreciating the charm of any intellectual pursuit whatever. For a time, however, things went on smoothly. In October the father and son once more visited Milan for the preparation and production of the new opera, Lucio Silla, which was produced at Christmas with a success quite equal to that of Mirabile, and ran between twenty and thirty nights.

In the meantime Wolfgang continued to produce new works with incredible rapidity. In 1775 he composed an opera for Munich, La Finta giardiniera, produced on the 13th of January. In the following March he set to music Metastasio's dramatic cantata, II Re pastore. Concertos, masses, symphonies, sonatas and other important works, both vocal and instrumental, followed each other without a pause. And this fertility of invention, instead of exhausting his genius, seemed only to stimulate it to still more indefatigable exertions. But the pecuniary return was so insignificant that in 1777 Leopold Mozart asked the archbishop for leave of absence for the purpose of making a professional tour. This was refused on the ground of the prelate's dislike to "that system of begging." Wolfgang then requested permission to resign his appointment, which was only an honorary one, for the purpose of making the tour with his father. The archbishop was furious; but the plan was carried out at last, and on the 23rd of September the mother and son started for Munich. The results were not encouraging. Leopold hoped that his son, now twenty-one years old, might obtain some profitable court appointment; but in this he was disappointed. And, worse still, poor Wolfgang fell in love at Mannheim with Aloysia Weber, a promising young vocalist, whose father, the prompter of the theatre (uncle of the great composer Weber), was very nearly penniless. On hearing of this Leopold ordered his wife and son to start instantly for Paris, where they arrived on the 23rd of March 1778. Wolfgang's usual success, however, seemed on this occasion to have deserted him. His reception was a cold one; and, to add to his misery, his mother fell seriously ill and died on the 3rd of July. Reduced almost to despair by this new trouble, he left Paris in September, rested for a while on his way home in Mannheim and Munich, was received by Aloysia Weber with coldness almost amounting to contempt, and in June 1779 returned to Salzburg, hoping against hope that he might make some better terms with the archbishop, who relented so far as to attach a salary of 500 florins (about £50) to his "concertmeister's" appointment, with leave of absence in case he should be engaged to write an opera elsewhere.

Two years later the desired opportunity presented itself. He was engaged to compose an opera for Munich for the carnival of 1781. The libretto was furnished by the abate Varesco, court chaplain at Salzburg. On the 20th of January 1781 the work was produced under the title of Idomeneo, re di Creta, with triumphant success, and thenceforth Mozart's position as an artist was assured; for this was not only the finest work he had ever written but incontestably the finest opera that had ever yet been placed upon the stage in any age or country.

And now the archbishop's character exhibited itself in its true colours. Art for its own sake he utterly disdained; but it flattered his vanity to retain a famous artist in his service with the power of insulting him at will. On hearing of the success of Idomeneo he instantly summoned the composer to Vienna, where he was spending the season. Mozart lost not a moment in presenting himself, but he soon found his position intolerable. That he should be condemned to dine with his patron's servants was the fault of the age, but the open disrespect with which the lowest menials treated him was due to the archbishop's example. His salary was reduced from 500 to 400 florins, he was left to pay his own travelling expenses, and he was not permitted to add to his means by giving a concert on his own account or to play anywhere but at the archiepiscopal palace. Archbishop Hieronymus was hated at court, and most of all by the emperor Joseph, who, on retiring to Laxenburg for the summer, did not place his name on the list of invited guests. This offended him so deeply that he left Vienna in disgust. The household were sent on to Salzburg, but Mozart was left to find lodgings at his own expense. Thereupon he sent in his resignation; and for this act of contumacy was insulted by the archbishop in terms too vulgar for translation. He persevered, however, in his resolution, taking lodgings in a house rented by his old friends the Webers, and vainly hoping for pupils, since Vienna at this season was perfectly empty. Happily he had a sincere though not a generous well-wisher in the emperor, and a firm friend in the archduke Maximilian. By the emperor's command he wrote a German opera, Die Entführung aus dem Serail, which on the 16th of July 1782 was received with acclamation, and not long afterwards was performed with equal success at Prague. This great work raised the national "Singspiel" to a level commensurate with that which Idomeneo had already attained for the Italian "opera seria."

The next great event in Mozart's life was not what one would have wished for him. Though Aloysia Weber had long since rejected him, his renewed intimacy with the family led to an imprudent marriage with her younger sister, Constance, a woman neither her equal in intellect nor his superior in prudence. The wedding took place at St Stephen's on the 16th of August 1782. By the end of the year the thriftless pair were deeply in debt. Mozart composed incessantly, played at numberless concerts, and was in greater favour than ever at court and with the nobility; but to the last day of his life his purse was empty. He had, however, many kind friends, not the least affectionate of whom was the veteran Haydn, who was sincerely attached to him. With Gluck he was on terms of courteous intercourse only. Salieri detested him, and made no secret of his dislike.

Mozart's next dramatic venture was a German singspiel in one act, Der Schauspieldirektor, produced at Schönbrunn, on the 7th of February 1786. Not quite three months later, on the 1st of May, he produced his marvellous Le Nozze di Figaro, the libretto for which was adapted from Beaumarchais by the abbé da Ponte. The reception of this magnificent work was enthusiastic. But Vienna was a hotbed of intrigue. Everything that could
be done by jealous plotters to mar the composer's success was done, and that so effectively that Mozart declared he would never bring out another opera in the city which treated him so meanly. Fortunately, Figaro, like Die Entführung, was repeated with brilliant success at Prague. Mozart went there to hear it, and received a commission to write an opera for the next season, with a fee of 100 ducats. Da Ponte furnished a libretto, founded on Tirso de Molina's tale, El Convidado de piedra, and entitled Il Don Giovanni. By the 28th of October 1787 the whole was ready with the exception of the overture, not a note of which was written. This circumstance has led to the idea that it was composed in haste, but it is certain that Mozart knew it all by heart and transcribed it during the night from memory, while his wife told fairy tales to keep him awake.

The opera was produced on the 29th of October with extraordinary effect, and the overture, though played without rehearsal, was as successful as the rest of the music. Yet, when reproduced in Vienna, Don Giovanni pleased less than Salieri's comparatively worthless Tarare.

On returning to Vienna Mozart was appointed kammercomposer to the emperor, with a salary of 800 gulden (£80). In April 1789 he accompanied Prince Lichnowski to Berlin, where King Frederick William II. offered him the post of "kapellmeister" with a salary of 3000 thalers (£450). Though most unwilling to quit the emperor's service, he informed him of the offer and requested leave to resign his appointment in Vienna. "Are you going to desert me, then?" asked the emperor; and Mozart, wounded by the reproach, remained, to starve. The emperor now commissioned Mozart to compose another Italian opera, which was produced on the 26th of January 1790 under the title of Così fan tutte. Though the libretto by Da Ponte was too stupid for criticism, the music was delicious, and the opera would probably had a long run but for the emperor's death on the 26th of February. In March 1791 Mozart consented to write a German opera upon an entirely new plan for Schikaneder, the manager of the little theatre in the Wieden suburb. The piece was to be addressed especially to the Freemasons, and to contain ceaseless allusions both in the words and music to the secrets of the brotherhood. Deeply interested in the affairs of a body of which he was himself a member, Mozart excelled himself in this new work, which took shape as Die Zauberflöte. For a stronger labour by a brilliant artistic success, but Schikaneder alone reaped the financial benefit of the speculation.

Before the completion of Die Zauberflöte a stranger called on Mozart, requesting him to compose a Requiem and offering to pay him 1000 ducats if he mastered it. Mozart, in the heat of superstitious fear, believing that the messenger had been sent from the other world to forewarn him of his own approaching death. Meanwhile he received a commission to compose an opera, La Clemenza di Tito, for the coronation of the emperor Leopold II. at Prague. He worked incessantly and far beyond his strength. The coronation took place on the 6th of September, and its splendours threw the opera very much into the shade. Die Zauberflöte was produced on the 30th of September and had a splendid run. But the Requiem still remained unfinished; the stranger therefore made another appointment, paying a further sum in advance. Mozart worked at it unremittingly, hoping to make it his greatest work. In the Requiem he surpassed himself, but he was not permitted to finish it. When the stranger called the third time the composer was no more. The score of the Requiem was reverently completed by Süssmayer, whose task may have been simplified by instructions received from Mozart on his deathbed. It is now known that the work was commissioned by Count Walsegg, who wished to perform it as his own.

Mozart died on the 5th of December 1791, apparently from typhus fever, though he believed himself poisoned. His funeral was a disgrace to the court, the emperor, the public, society itself. On the afternoon of the 6th his body was hurried to a pauper's grave; and because it rained, Van Swieten, Süssmayer, and three other "friends" turned back and left him to be carried to his last long home alone.

(Mozart) work falls conveniently into three periods, though O. Jahn makes out, more accurately, five. Our first period may be said, in sober seriousness, to begin at the age of five and to merge into the second somewhere about the age of sixteen or seventeen. It was fortunate that the infancy of the sonatas (q.v.) coincided with the infancy of Mozart; for while this coincidence gave his earliest attempts a marvellous resemblance to the work of the fully-grown masters of the time, it secured for his mental activity a healthy and normal relation to the musical world which infant prodigies can never attain in a modern artistic environment. The little pieces composed by Mozart in his fifth and sixth years are a fascinating study in the unwavering progress made by a child who masters every step, not by some miraculous intuition that enables him to dispense with learning, but by a hardly less miraculous directness of thought that prevents him from either making the same mistake twice or exactly repeating a form once mastered. The violin sonatas written in London and Paris at the age of seven in no way fall below the accepted standards of the period, while they already show that variety of invention and experiment which, by the time he was twelve, caused some sober-minded critics to regard him as a dangerous person. His studies in the severer contrapuntal forms speedily gave him the greatest technical mastery of choral music attained since Bach; and more than one stray piece of church music, or movement from a mass or litany, written before he was fifteen, deserves to take rank as a true masterpiece of which the date is immaterial. At the age of fifteen we see a loss of freshness, especially in the numerous operas which show at its worst that hopeless condition of operatic art from which only Gluck's most drastic reforms could rescue it. Fortunately, Mozart had at fifteen acquired more than enough technique to rest upon; and thus the growing boy could keep his spirits up, continuing his public successes and indulging his easy sense of mastery, without putting a strain upon his brain which nature need revenge then or afterwards.

Lucio Silla, though loaded with conventional bravura arias, nevertheless shows him approaching the age of seventeen with clear signs of a man's power, and in higher qualities than mere variety and fancy. Some of its recitatives and choruses strike a solemn dramatic note hitherto undreamt of in stage music, except by Gluck. La Fiària giardini era first gave Mozart scope for the exercise of his wonderful stage-craft and power of characterization. Though it has not the stage, yet it marks the beginning of his best masses, written in F and D, written in the same year, mark the close of his first really representative period as a composer of church music. It is, however, difficult to draw such lines definitely; for there is no period of Mozart's career in which he did not practise all art-forms at once; and the difficulty of drawing inferences as to the relative importance of different forms in his intellectual development is increased by his invariable mastery, which seems to depend neither on method nor on inspiration. Most of the pianoforte sonatas and many of the best-known violin sonatas belong to his early manhood. To the same period also belong those unfortunate masses which, together with several spurious works, were at one time so popular, and have since been accepted as evidence that he had not the depth of feeling and earnestness necessary for church music. Idomeno and Die Entführung are currently regarded as quite early works, but they are later than any of the masses except the great unfinished work in C minor, and there is some really great church music of his later period in the shape of stray pieces, litanies and vespers (i.e. collections of psalms sung at evening service) which is almost totally neglected, and which shows a consistent solemnity and richness of style no less in keeping with Mozart's new artistic developments than worthy of the glories of Handel and Bach.

Idomeno is the only opera of Mozart which unmistakably shows the influence of Gluck; because, with the exception of La Clemenza di Tito, it is the only opera seria by which Mozart is
known; and only a serious opera on a classical subject could furnish occasion for Gluck's phraseology and range of feeling to appear at all. How profoundly and independently Mozart seizes Gluck's method and style may best be seen by comparing the oracle scenes in Idomeneo and Alceste. In the management of the chorus, however, Mozart has, as was to be expected, incomparably the advantage. He has all, or rather more than all, Gluck's power for portraying panic and managing, by the motion of his music, the flight of a crowd; but he also has an inexhaustible harmonic and contrapuntal invention which lay beyond Gluck's scope.

The problems of comic opera presented a far more fruitful field. In Die Entführung he speedily showed a dramatic grasp for which opera seria, in spite of all the influence of Gluck, gave him no scope. He had a wonderful feeling for character, and did not imagine, like many French and other disseminators of musical-dramatic ideas (including, in moments of weakness, even Gluck himself), that the expression of character in music was a mere matter of harping on special types of phrase. His melodic invention was clearly and subtly characteristic without mannerism. It is of hardly minor importance that his own literary sense was far higher than that of many a writer of ostensibly superior general culture; and that Osmín, the most living figure in Die Entführung, is Mozart's creation, words and all.

After Die Entführung, Mozart's record is a series of masterpieces, accompanied, but not interrupted, by a running commentary of pièces d'occasion. With rare exceptions, everything he writes illustrates the perfect solution of an art-problem, and he often achieves an artistic triumph with the most eccentric materials. The modern organist can find since Bach no grander piece in his repertory than the two fantasies which Mozart wrote for the barrel of a musical clock. Shortly before his death he wrote a beautiful adagio and rondo for the glass harmonica, to which he devised the curious but eminently natural accompaniment of flute, oboe, viola and violoncello. And when at an earlier period it occurred to him to write some processional music for two flutes, five trumpets and four drums, the result, although not artistically important, might well have seemed to indicate long experience in handling the combination. His work in the larger instrumental forms is further discussed in the articles Sonata Forms and Instrumentation. While Mozart's treatment of form has often been attacked as conventional, and his range of thought despised as childish, his instrumentation and general sense of euphony are at the present day more unreservedly admired by the most progressive propagandists than anything else in classical art.

Mozart's later operas, from Figaro onwards, represent the nearest approach to a perfect art-form attainable in pre-Wagnerian opera. What he might have attained in serious opera had he been spared to see the solemn triumphs the French operatic stage realized in the austere sincerity of Cherubini and Mélhul it is impossible to guess. But we cannot doubt that a Mozart of yet riper experience than we have known would have given tragic opera a history in which Fidelio did not stand in lonely splendor. But even this was not all; the art form was only temporarily rescued from the tyranny of bravura singers by Gluck. After Idomeneo he handled it only once, at the very close of his career, and then, as if to seal its fate, in a pièce d'occasion with an impossibly dull and unsympathetic libretto (La Clemenza di Tito). For comedy, however, his harmonic and rhythmic range was perfectly adapted; and in Figaro he had the advantage of a libretto which was already a finished literary product of consummate stagecraft before it ever became an opera. The perpetual surprises of its absurdly complex intrigues impose no real strain, for no one attempts to follow them; but they keep every character on the stage in a state of excitement which is so heightened and differentiated by the music that, while Beaumarchais's Mariage de Figaro has its modest but definite place in literature, Mozart's Figaro is, with all its lightness of touch, one of the most ideal classics in all art. The subject is not edifying; but Mozart does not analyse from that point of view. His characters are irresponsible, mischievous and fairy-like. Theirs is the world described by Lamb—"the Utopia of gallantry, where pleasure is duty and the manners rival freedom."

In Don Giovanni the matter is less clear. Mozart rose, not only in the music of the ghostly statue, but also in the music of Donna Anna and Donna Elvira, to heights that can only be called sublime; yet he never lost sight of the true methods of that comedy of gallantry to which Don Giovanni stands in some sense as a grotesque tragic finale. It is the business of an artistic intellect to grasp the artistic possibility of a world in which the "Utopia of gallantry" is at war with a full-blooded and incipiently moral humanity until the critical moment determines, not the breaking up of the artistic unity, but the right conclusion of the story. If it is absurd to treat Donna Anna and Donna Elvira as Wagnerian heroines, and so to complain of the inadequacy and conventionality of much of their utterances and attitudes; so, also, is it no less absurd to regard them as "secretly rather gratified than otherwise to be on Don Giovanni's list." Donna Elvira has suffered more cruelly from stolidly tragic singers and no less stolidly flippant critics than she ever suffered from Don Giovanni himself. She comes upon the stage expressing herself in thoroughly country phrases as all the old that the formulas of Italian opera are inadequate for the expression of her sorrows. Look at the sfogando in the second violins at the words Ah se ritrovo l'empio. Mozart is depicting a young girl facing a position she does not in the least understand; expressing herself in stereotyped phrases as much from inexperience of their meaning as from lack of anything that may better say what she really feels. What Mozart's music with exquisite humour and simplicity expresses is as yet nothing more serious than the wish to scratch Don Giovanni's eyes out; as soon as his character is revealed to her in Leporello's comic aria of the "catalogue," she determines that others at all events shall not suffer as she has suffered; and from that moment her character steadily develops in seriousness and dignity. She is not all strength, and Don Giovanni fools her to the top of her bent; but nevertheless Mozart realizes, on hints of which the librettist was hardly conscious, a consistent scheme of development as dramatic as it is in keeping with the most sublime possibilities of comic opera. Yet it is a common practice to insert Elvira's last confession of weakness, the aria Mi tradi, immediately after Leporello's catalogue aria! Perhaps the first place where an intelligent tradition of Mozart as a comic genius of the highest type has been restored is Munich, where the standard set under the conductorship of Richard Strauss will not soon be forgotten.

In Coste fan tutte Mozart's struggles with an absurd libretto show even clearer evidence of the accuracy and power of his genius than when he is working under conditions where success is possible. Space forbids our dwelling further on this subject, nor can we do more than glance at his last great opera, Die Zauberflöte. Beethoven thought it his greatest work; for the simple literal-minded sincerity with which Beethoven regarded the question of operatic libretto made Figaro frivolous and Don Giovanni scandalous in his sight. Mozart's very serious interest in freemasonry, which is in its solemn ritual furnished an edifying subject (though it is not more than a possibility) of the existing state of church music, inspired him with the most sublime ideas hitherto brought upon the operatic stage. He was further stimulated by the feeling that freemasonry was to some extent a persecuted institution; and the circumstance that his librettist was a skilful stage manager secured for him that variety of action and effectiveness of entry and exit, compared with which an intelligible plot is of almost negligible importance as a source of inspiration to the classical composer, or even as a means of retaining popular favour. Thus Die Zauberflöte is an achievement unique in opera; combining as it does the farcical gorgeousness of a pantomime with the solemnity of a ritual and the contemporary interest of a political satire.

From the solemnity of masonic ritual there is but one step to that most pathetic of unfinished monuments, Mozart's Requiem. The finished portions of this work contain the most sublime and perfect church music between Bach and the Missa solemnis of
Beethoven. The unauthentic portions, supplied by Süssmayer, are so well designed that even their comparatively slightness of material hardly militates against the suggestion that he may have had some inkling of Mozart's intentions. In particular, the return of the first number at the words Lux aeterna, which enables Süssmayer to end with ten pages of authentic Mozart, is splendidly placed (though Mozart is reported to have contemplated an independent final number); while the latter part of the Lacrimosa, though not in Mozart's handwriting, must surely have been dictated by him. The instrumentation of the incomplete numbers is based for the most part on highly authentic evidence, though there are doubtful points; but that of the supplied numbers, especially the Benedictus, is far below the intellectual level of their design. In this, his last work, as in many wonderful polyphonic experiments immediately before it, Mozart displays his wonderful inventive faculty, for which would undoubtedly have had an influence even more powerful on the history of music as being embodied in works surpassing his ripest known achievements as these surpass the marvellous productions of his childhood. Nevertheless, what he has given us is unique, and the intelligent love of Mozart's work is a liberal education in the meaning of art.

Mozart's extant works (as catalogued by Köchel in 626 items, beginning with minuets written at the age of four and ending with the unfinished Requiem, including the Regina caeli, the great unfinished Mass in C minor); 8 sets of vespers and litanies; 40 smaller Latin pieces of church music; 6 cantatas and oratorio works, of which the finest, Donnizetti, is adapted from the C minor Mass; 17 "sinfonias" or concert concerti for organ and an organ-lofted choir, for use in church; 23 operas (including fragments and operettas); 66 arias and other pieces for insertion into operas or for concert use; 41 songs with piano forte accompaniment; 23 canons; mostly by Mozart; 17 piano forte concertos; 3 concerti for oboe and a Handelian suite (unfinished); 22 smaller piano forte pieces; 36 cahenas to his own piano forte concertos; 11 works for piano forte in four hands; 11 sonatas; 3 arrangements in various combinations; 8 piano forte trios; 2 piano forte quartets; 1 quintet; 2 duets for violin and viola; 2 string trios; 29 string quartets; 2 quartets for flute and strings; 1 quartet for oboe and strings; 9 concerto movements for the singular combination of 1 violin, 2 violas, violoncello and horn;泉水 is also the famous clarinet quintet; 49 symphonies; 33 casations, serenades and divertimenti, many for the oldest orchestral or solo combinations; 27 smaller orchestral and other pieces, also often for strings, comprising beauty; 29 sets of orchestral dances; 6 violin concertos (the 6th is either quite spurious or extremely corrupt) and 4 single violin movements; 2 double concertos for 2 violins or 2 violins and violin and viola; 10 concertos and concert pieces for various wind instruments (flute, horn, bassoon, clarinet, flute and harp); 27 piano forte concertos (including one for 2 and for 3 pianofortes) and a concerto for two pianos, as well as a number of solo pieces that were written them particularly promising, as if Mozart was full of ideas that were in advance of even his mastery of form; there is, for example, a magnificent and comparatively early opening tutti for a double concertant in A, and a very large string quartet movement in A (probably a finale), which breaks off at an exciting moment at the beginning of its development.

No composer's reputation has suffered more from forgeries and false attributions than Mozart's, and the role begun during the lifetime of his widow is not yet ended at the present day. The concertante for 4 wind instruments which recently went triumphantly round the orchestral societies of Europe as a long-lost work written by Mozart himself, and which it is not hard to believe was written by Mozart's pupils in 1917, its alleged date.

Mozart's extant works (as catalogued by Köchel in 626 items, beginning with minuets written at the age of four and ending with the unfinished Requiem, including the Regina caeli, the great unfinished Mass in C minor); 8 sets of vespers and litanies; 40 smaller Latin pieces of church music; 6 cantatas and oratorio works, of which the finest, Donnizetti, is adapted from the C minor Mass; 17 "sinfonias" or concert concerti for organ and an organ-lofted choir, for use in church; 23 operas (including fragments and operettas); 66 arias and other pieces for insertion into operas or for concert use; 41 songs with piano forte accompaniment; 23 canons; mostly by Mozart; 17 piano forte concertos; 3 concerti for oboe and a Handelian suite (unfinished); 22 smaller piano forte pieces; 36 cahenas to his own piano forte concertos; 11 works for piano forte in four hands; 11 sonatas; 3 arrangements in various combinations; 8 piano forte trios; 2 piano forte quartets; 1 quintet; 2 duets for violin and viola; 2 string trios; 29 string quartets; 2 quartets for flute and strings; 1 quartet for oboe and strings; 9 concerto movements for the singular combination of 1 violin, 2 violas, violoncello and horn; another is the famous clarinet quintet; 49 symphonies; 33 casations, serenades and divertimenti, many for the oldest orchestral or solo combinations; 27 smaller orchestral and other pieces, also often for strings, comprising beauty; 29 sets of orchestral dances; 6 violin concertos (the 6th is either quite spurious or extremely corrupt) and 4 single violin movements; 2 double concertos for 2 violins or 2 violins and violin and viola; 10 concertos and concert pieces for various wind instruments (flute, horn, bassoon, clarinet, flute and harp); 27 piano forte concertos (including one for 2 and for 3 pianofortes) and a concerto for two pianos, as well as a number of solo pieces that were written them particularly promising, as if Mozart was full of ideas that were in advance of even his mastery of form; there is, for example, a magnificent and comparatively early opening tutti for a double concertant in A, and a very large string quartet movement in A (probably a finale), which breaks off at an exciting moment at the beginning of its development.

Many genuine works are known in spurious forms; thus the motet Splendente deus is an unauthorized arrangement of a chorus from König Thamos, and most of the flute-music mentioned in the article Flute in Grove's Dictionary (new ed.) consists of spurious arrangements, while several important genuine works are ignored.

(M. D. T.)

MOZDOK, a town of Russia, in Caucasus, and in the province of Terek, on the left bank of the river Terek, 605 ft. above sea-level, in 43° 41' N. and 44° 39' E., 30 m. N. of Vladiikavkaz. The population, 8760 in 1883, numbered 14,583 in 1897, and consisted of Kabardians, Chechens, Ossetes, Georgians and Armenians. Built in 1763 by the prince of Kabardia, Mozdok soon became an important point in the Russian advance towards the Caucasus, and was fortified. In 1816 it was attacked by the Caucasian pasha Semt Gaud, and 3000 mountaineers. The melons and water-melons of Mozdok are widely famed; and vine-growing and silk-worm breeding prosper.

MOLEY, JAMES BOWING (1813-1878), English theologian, was born at Gainsborough, Lincolnshire, on the 15th of September 1813, and was educated at Oriel College, Oxford. He was elected to a fellowship at Magdalen in 1840. He took an active part in the Oxford movement, but could no more follow Newmian into the Roman communion "than fly." He was joint editor of the Christian Remembrancer, but withdrew from the position because of his substantial agreement with the famous Gorham decision. He was one of the earliest supporters of the Guardian.

In 1856 he became vicar of Shoreham, in 1869 canon of Worcester, and in 1871 regius professor of divinity at Oxford. He died at Shoreham on the 4th of January 1878.

He wrote A Treatise on the Augustinian Doctrine of Predestination (1842); The Principles of Baptismal Regeneration (1850); A Review of the Baptismal Controversy (1852); Subscription to the Articles: A Letter (1853); Lectures on Miracles, being the Bampton Lectures for 1865; and Ruling Ideas in Early Ages and their relation to the Old Testament Faith (1877). Essays, Historical and Theological, appeared in 1878 (2 vols.), with a biographical preface by his sister Anna, who also edited some of his Letters (1884).

MOLEY, THOMAS (1806-1853), English divine and writer, was born at Gainsborough in 1806, the son of a bookseller and publisher in that town. From Charterhouse school he proceeded to Oriel College, Oxford, where he became the pupil, and subsequently the intimate friend, of John Henry Newman. In 1831 he was ordained, and became, in 1836, rector of Cholderton, Wilts. He was, from its beginning, a strong supporter of the Tractarian movement, and after contributing for some time to the British Critic, the chief organ of the movement, succeeded Newman as editor in 1841. In 1843 he was on the point of joining the Roman Catholic Church. Newman, however, strongly advised him to take two years to reflect, and long before Newman had claret in hand had determined to remain an Anglican. In 1844 he began to write leading articles in the Times, and continued to do so regularly for many years. In 1847 he resigned his country living and settled in London, but in 1868 accepted the living of Pymble, Devonshire. From 1876-1880 he was rural dean of Ottery St Mary's, Devon. He resigned his living in 1880, and removed to Cheltenham, where he died on the 17th of June 1893.

He was the author of Reminiscences, chiefly of Oriel, and the Oxford Movement, published in 1882.

MPONGWE (Pongo), a settled Bantu people of the Gabun, West Africa, constantly confused with the Mangawe or Fang (q.v.). The Mpongwe, who call themselves Ayogo or "the Wise," have a rich collection of national songs, myths and traditions, and the tribal elders know the "Hidden Words," a kind of secret language of unknown origin. Their language, a Bantu dialect, has been the means of communication between the tribes of the interior and the Europeans. The family organization is intricate and very similar to the Roman patria potestas; wives, children and slaves being all subservient to the father, who alone is really free. They practise the poison ordeal, and reverence vague and malignant spirits who require propitiation by offerings and ceremonies. The ghosts of the dead are especially feared.

MTSENSK (popularly Amchensk), a town of Russia, in the government of Orelov, on the navigable Zuzha River, 17 m. from its confluence with the Oka, and on the Moscow & Kursk railway, 32 m. N.E. of the city of Orelov. Pop. (1900), 9300. It is
MUCH WENLOCK, a market town in the municipal borough of Wenlock (q.v.), and the Ludlow parliamentary division of Shropshire, England, 153 m. N.W. from London on the Great Western railway. It lies at the north end of Wenlock Edge, a range running south-west from the Severn valley. A priory was founded here as a nunnery by St Milburg, granddaughter of Penda, about 680, and after being destroyed by the Danes was refounded by Leofric in 1017. Afterwards it was remodelled by Roger de Montgomery for Cluniac monks. There are beautiful remains of the priory church, chiefly Early English; but there is a chapter-house of ornate Norman work. The priory house, still inhabited, is a remarkable specimen of 15th-century work, adjoining and incorporating remains in earlier styles. The parish church of Holy Trinity, close to the ruins, is of mixed styles from Norman onwards. The village is a small one with a church, hall, and almshouses. It is an agricultural, mainly agricultural, but there are limestone quarries in the neighbourhood. Wenlock received the grant of a market from Henry III. in 1224. It was incorporated by Edward IV. in 1448, when it also received the privilege of returning members to parliament, but in 1885 it ceased to have separate representation.

MUCIANUS, LICINUS, Roman general and statesman, lived during the 1st century A.D. His name shows that he had passed by adoption from the Mucian to the Licinian gens. About A.D. 55 he was sent by Claudius, who had become suspicious of his intimacy with Messalla, to Armenia with Domitian Corbul. Under Nero he regained the imperial favour. After the death of Galba (69), Mucianus and Vespasion (who was at the time in Judea) both swore allegiance to Otho, but when the civil war broke out Mucianus persuaded Vespasion to take up arms against Vitellius, who had seized the throne. It was agreed that Vespasion should stay behind to settle affairs in the East, while Mucianus made his way through Asla Minor and Thrace to aec Vitellius. He laid siege to the last stronghold of Vespasion and four of Domitian, Vespasion's son, at the head of affairs, but until the arrival of Vespasion the real master of Rome was Mucianus. But he never wavered in his allegiance to Vespasion, whose favour he retained in spite of his arrogance. As no mention is made of Mucianus during the reigns of Titus or Domitian, he probably died during the reign of Vespasion. He was a clever writer and historian. He made a collection of the speeches and letters of the Romans of the older period, probably including a corpus of proceedings of the senate (Acta senatus), and was the author of a work, chiefly dealing with the natural history and geography of the East, which is often quoted by Pliny the Elder, especially for fabulous statements.

See monograph by L. Brun (Leipzig, 1870).

MUCULAGE (from Late Lat. mucugo, a mousy juice, from mucere, to be mousy), a term which denotes a viscous or glutinous mixture of water and any gummy vegetable substance (see Gum). Mucilages are useful in medicine as vehicles for various insoluble and other drugs, and in the arts as thickeners (in calico-printing, dyeing, &c.). The British pharmacopoeia contains the mucilages of acacia and tragacanth.

MUCHEN (Ger. Muchen, i.e. canting bigots, hypocrites), the chief town of the followers of the teaching of Johann Heinrich Schönberr (1770-1836) and Johann Wilhelm Ebel (1784-1861). Schönberr, the son of a non-commissioned officer at Memel in Prussia, was educated at the university of Königsberg, where at that time the theological faculty, under the influence of Kantian idealism, was strongly rationalist in tendency. The lad, who was miserably poor, was dissatisfied with a philosophy which stopped short of an explanation of the "thing in itself," and, having been reared in the strictest orthodoxy, he set to work to develop, with the aid of the Bible, a philosophy of his own. In the end he believed himself to have reached ultimate knowledge, and became the prophet of a dualistic theosophy, so closely analogous to Gnosticism that it might have been taken for a deliberate revival, had not Schönberr's lack of education precluded any such idea. Among his converts was Ebel, who from 1810 onwards gained a great reputation in Königsberg as an earnest preacher of the orthodox doctrines of sin, grace, and redemption, and in 1816 was appointed "archdeacon," i.e. principal pastor, at the old church in Königsberg. In the pulpit Schönberr led an open attack on the "papacy" of the church; he initiated, to whom in private he taught Schönberr's doctrines. Schönberr himself sank into the background, and eventually died in 1826. But Ebel continued his teaching, and was joined in 1827 by Heinrich Diestel, also a Lutheran pastor of Königsberg. They became father confessors to a wide circle of silly fashionable people in the Prussian capital. In view of their peculiar teaching as to "the purification of the flesh," which involved the minute regulation of the intercourse of married people, scandal was

1 Schönberr distinguished two primal powers or principles—one male and active, the other female and passive—having both personal and collective existence; he called them Light and Darkness, Fire and Water. They moved freely in the void, and from their ultimate contact God and the world sprang into being. Evil came into existence owing to the fall of Lucifer, a Light-being created by God, who in revenge lent his aid to the powers of Darkness. Sin came with the Fall of Man; and this infection, inherited with the blood, necessitated redemption in order to restore the harmony of the primal powers. This was the work of Christ, who descended into a world that had become divided into children of Light and children of Darkness. The power of the Holy Ghost, emanating from Christ, perfects the higher natures in whom Christ's "law of righteousness" is represented and who to a certain extent share in his being, becomes their duty to obtain control over the lower natures so as to struggle against the powers of Darkness in them—powers which can be overcome by prayer, fasting, and self-mortification generally. The end was near and the triumph of the Light assured. Anti-christ (Napoleon) had already appeared, and when Christ came he would find no faith on the earth (Luke xviii. 8) because faith would be swallowed up in knowledge.
inevitable. Matters came to a head in 1835, when Count Finckenstein, himself formerly an initiate, denounced the two pastors and accused them of immorality. Dietzel wrote two violent tirades against the count, who brought an action for slander and won it. The evidence taken in the case was then laid before the consistory, and proceedings followed which became famous as the "Königsberger Religionsprozesse" (1835-1841), ending in sentences of deprivation on both Dietzel and Dietzel. The charges of actual immorality were dismissed; but there is no doubt that some of their followers established practices akin to those of the Agapemone and the Perfectionists. Some of them migrated to Brazil, where in 1874 at Port-Alegre a company of them came into collision with the military.

See also Victor Cousin (1809-1879), Beheroy Dixon, Spiritual Wires (1868); and, more especially, the article on Schönkerr, by P. Tschackert, in Herzog-Hauck, Redenzyklopädie (3rd ed., Leipzig, 1906), vii. 676.

MUCUNA, a genus of twining plants, belonging to the natural order Leguminosae, and natives of the tropics. M. pratensis is popularly known as cowhage or cowitch, a corruption of the Hindu Knavach. It is a tall annual climber with large dark purple pea-like flowers, and golden-brown velvet pods recalling those of the sweet pea, the hairs or bristles on which often raise blisters on the skin. It is common in the tropical regions of India, Africa and America, and the hairs on the pod have long been used in medicine as a vermifuge.

MUDANIA (anc. Acone Myrlea), a town of Asia Minor, on the south coast of the Sea of Marmora, and the port of Brusa. It is connected with Brusa by a railway and a carriage road, and with Constantinople by steamers. Olive oil is produced. Pop., 5000, of which two-thirds are Greeks.

MUDHOL, a native state of India in the southern division of Bombay. Area, 368 sq. m.; pop. (1901), 63,001; revenue, £20,000. It was a Maharrati principality dating from Mahomedan rule before the rise of Sivaji. The family name of the chief is Ghoparde. The town of Mudhol stands on the left bank of the Ghatprabha; pop. (1901), 8359.

MUDIE, CHARLES EDWARD (1818-1890), English publisher and founder of Mudie's Lending Library, was born at Chelsea on the 18th of October 1818, the son of a secondhand bookseller and newsagent. In 1840 he established a stationery and book-selling business in Bloomsbury, London. He was the first publisher of James Russell Lowell's poems in England, and of Emerson's Man Thinking. In 1842 he began to lend books. This department proved so successful that in 1852 he moved his "Select Library" to larger premises in New Oxford Street, London. In 1860 these premises were substantially enlarged, and branches of the business established, and in 1864 Mudie's was converted into a limited company. Mudie himself died on the 28th of October 1890.

MUFF, an article of outdoor apparel, open at either end, for holding the hands in and keeping them warm, generally made of fur, but also of velvet, silk, &c. Muffs are now only used in England by women, but in the 17th and 18th centuries were fashionable for men. In Roman times the place of the glove was taken by long sleeves (manicae) reaching to the hand, and in winter special sleeves of fur were worn (cf. Cic. Phil. ii. 11, 26). In Medieval Latin we find the word muffsulae, defined by Du Cange (Gloss. s.v.) as chirotheca pelletiae et hibernae. He quotes from a cartulary of the year 817, of the issuing to monks of sheepskin coverings to be used during the winter. They may have been, as the Roman certainly were, separate coverings for each hand, although the cartulary cited also distinguishes the glove for summer from the muffsulae for winter wear. The Fr. mousse meant a thick glove or mitten, and from this the Du. moff, Woolon muffe, and thence Eng. "muff," are probably derived. From the Fr. mousse have come the various uses, verbal and substantival, of "muff," viz. to wrap round for protection, for deadening sound &c., and for a chamber or receptacle in a furnace to protect objects from contact with fire while exposed to heat. The slang use of "muff" for a clumsy, awkward person is of late origin. It appears in the middle of the 19th century.

MUFFLING, FRIEDRICH KARL FERDINAND, FREIHERR von, called WEISS (1775-1851), Prussian general field marshal, was born on the 23rd of July 1772, and of the Prussian army in 1790. In 1799 he contributed to a military dictionary edited by Lieutenant W. von Leipziger, and in the winter of 1802-1803, then being a subaltern, he was appointed to the newly-formed general staff as "quartmaster-lieutenant." He had already done survey work, and was now employed with survey duties under the astronomer F. X. von Zach (1754-1832). In 1805, when in view of a war with France the army was placed on a war footing, Muffling was promoted captain and assigned to the general staffs, successively, of General von Wartenstein, Prince Hohenlohe and Blücher. In 1806 he served under Hohenlohe, the duke of Saxe-Weimar, and Blücher, and was included in the capitulation of the latter's corps at Rattkau, after which he entered the civil service of the duke of Weimar. He rejoined the army at the outset of the War of Liberation in 1813, and was placed on the headquarters staff of Silesia. His business qualities and common sense were greatly valued, though the temperamental differences between Muffling and Gnesenau often led to friction, especially as the former was in a measure the representative of the antiquated "topographical" school of strategists, to whom (rightly in the main) the disaster of Jena was attributed. In the interval between the first occupation of Paris and the Hundred Days, Muffling served as chief of the staff to the Russian general Barclay de Tolly and to General Kleist von Nollendorf. He was Prussian commissioner at the duke of Wellington's headquarters in the Waterloo campaign, and was involved in the various controversies which centred round the events of the 16th of June 1815. After the final fall of Napoleon he served on the staff of the army of occupation in France, and was for some months military governor of Paris. He spent a part of his time on this mission in survey work, and was employed by Frederick William III, in his curious diplomatic missions. In 1821 he became chief of the general staff at Berlin, and though he has been accused of indulging his taste for topographical work at the expense of training for war, his work was not wasted, for he gave an excellent organization to the general staff, and executed elaborate and useful surveys. In 1829 he visited Constantinople and St Petersburg in connexion with negotiations for peace between Russia and Turkey. He took a prominent part in the military and civil history of Prussia, and from 1835 to 1847 was governor of Berlin. Failing health compelled his retirement in the latter year, and he died on the 16th of January 1851, at his estate of Ringhoien near Berlin.

Under the initials of C.W. von Weß, he wrote various important works on military art and history: "Operative Kriegs- und Feldzüge," 2 vols. 1806 (Weimar, 1807); marginalia on the archduke Charles's "Grundsätze der höherem Kriegskunst für die General der estieren Armee, und auf Rühle von Liliestern's Berichte über die Vorgänge bei der Hohenlocheschen Armee 1806; Die preussisch-russische Kampagne bis zum Waffenstillstande 1813 (Berlin, 1813); Geschichte der Armeen unter Wellington und Blücher 1815 (Stuttgart, 1817); Zur Kriegslehre der Jahre 1813-1814; die Feldzüge der schlesiischen Armee von der Beendigung des Waffenstillstandes bis zur Eroberung von Paris (Berlin, 1824); Betrachtungen über die grossen Operationen und Schlachten 1813-1815 (Berlin, 1825); Napoleon's Strategie 1803-1815 (Berlin, 1827); and an 1831 "Mudhol road on the lower Rhine (Berlin, 1834). Muffling was also the inventor of a system of surveying for maps. His reminiscences, Aus meinem Leben, were published at Berlin in 1851.

MUFF: a consulting canon-lawyer in Islam, who, upon application, gives fatwas (fetwas) or legal opinions on points of canon law (see MAHMOMEDIAN LAW). These are asked and given in strictly impersonal form, but the cadi, or judge, then applies them to the case and decides in accordance with them. In theory, any learned man whose opinion is respected and whose advice is sought can give fatwas. But generally in a Muslim state there are mufis specifically appointed by the government, one for each school of canon law in each place. Each of these renders opinions in accordance with the law-books of his school;

The use of the word for plain or civilian clothes worn instead of military or originally Angelicalian. It may have been suggested by the loose flowing robes of the stage "mufti," and thus implied any easy dress worn by an officer when out of uniform.
he has no scope for free interpretation; everything is fixed there, and he must follow the precedents of the elders. In Turkey there is a chief mufti, called the Sheikh al-Islam, whose office was created by the Ottoman sultan, Mahomed II., in 1453, after the capture of Constantinople. He is, in a sense, the head of the ecclesiastical side of the state, that controlled by canon law; while the grand vizier is at the head of secular matters. Although his powers are delegated by the sultan-caliph, and he is appointed and can be dismissed by him, yet in his fatwā-issuing power he is independent. The sultan may dismiss him before he has a chance to issue a fatwā; but if he once issues it the result is legally automatic, even though it means the deposition of the sultan himself. Thus it was by a fatwā of the Sheikh al-Islam that the sultan Abdul Hamid was deposed.

MUGGLETON, LODOWICKE (1600–1698), English sectarian, was born in Bishopsgate Street, London. His father was a farrier, but he himself was bred to be a tailor. In 1651 he began to have revelations, and to proclaim himself and his cousin John Reeve, whose journeyman he was, as the two witnesses mentioned in Rev. xi. 3. In 1652 they put out their "commission book" under the title The Transcendent Spiritual Treatise. An exposition of their doctrines was published in 1656 under the title of The Divine Looking-Glass. Among other views (besides the dualism which he held to distinguish the Trinity) he maintained that the distinction of the three persons in the Trinity is merely nominal, that God has a real human body, and that He left Elijah as His vicegerent in heaven when He Himself descended to die on the cross. Muggleton's opinions gained some notable adherents, but also called forth much opposition. In 1653 he was imprisoned for blasphemy, and twice (1660 and 1667) his own followers temporarily repudiated him. His attack on the Quakers drew forth William Penn's book, The New Witnesses proved old Heretics (1672). In 1677 Muggleton was tried at the Old Bailey, convicted of blasphemy, and fined £500. Reeve died in 1678, but Muggleton survived till 1698.

His collected works, including the posthumous Acts of the Witnesses, were published in 1756; and in 1832 some sixty Muggletonians subscribed to bring out a new edition of The Works of J. Reeve and L. Muggleton (in 3 vols. 4to). Even as late as 1846 The Divine Looking-Glass was reprinted by members of the then almost extinct sect. See A. Jessopp, The Coming of the Priests (1888).

MUGWUMP, in American political slang, a name applied to any independent voter, and especially to those independent voters in the Republican party who refused to support James G. Blaine, when nominated by that party for the presidency in 1884; as since adopted in England it usually means one who stays neutral and votes for no party. Originally "mugwump" (mok'wump) was a North American Indian word, in the Massachusetts dialect of the Algonquin, meaning "great man" (mogki, great; om-p, man); and in New England it was used of self-constituted politicians.

MUHAMMAD (Mohammed), a town of Persia, in the province of Azerbaijan, in 30° 26' N., 48° 11' E., on the Hafar canal, which joins the Karun with the Shatt el Arab, and flows into the latter 40 m. above its mouth at Fao and about 20 m. below Basra. It has post and telegraph offices, and a population of about 4000. With the opening of the Karun river, as far as Alhaz, to international navigation in 1889, Muhammar acquired great importance, and contributed a large share of the revenue to the government for £1500 per annum, rose considerably, and paid £2000 until taken over by the central customs department under Belgian officials in 1902. It is estimated that the value of the imports and exports into and from Muhammar, excluding specie, is about £3000,000 per annum, paying customs amounting to about £1000. Until 1847, when it definitely became Persian territory in accordance with art. ii. of the treaty of Erzerum, Muhammad was alternately claimed and occupied by Persia and Turkey, its ruler, an Arab sheikh, helping either power as he found it convenient. Since then the governor of the town and adjoining district has been a sheikh of the K'ab or Chab Arabs, a powerful tribe of the Shi'ah branch of Islam. At the close of the Anglo-Persian campaign in 1857 Muhammar was taken by a British force.

MÜHLBERG, a town of Germany, in Prussian Saxony, on the left bank of the Elbe, 8 m. below Riesa. Pop. (1905), 3386. It carries on a considerable trade by water in timber and corn. Mühlberg is famous for the victory gained here, on the 24th of April 1547, by the emperor Charles V. over the electors of Saxony, John Frederick.

See Lenz, Die Schlacht bei Mühlberg (Gotha, 1879); and Bertram, Chronik der Stadt Mühlberg (Torgau, 1864).

MÜHLBERG, HENRY MELCHIOR (1711–1787), German-American Lutheran clergyman, was born in Einbeck, Hanover, on the 6th of September 1711. When he was twelve years old his father, a member of the city council, died. The son entered the university of Göttingen in 1735, and his work among the poor of Göttingen led to the establishment of the present orphan house there. In 1738 he went to Halle to finish his theological studies; he was a devoted worker in the Franckesche Stiftung, which later served as a partial model for his great-grandson's community at St Johnland, Long Island. He was deacon at Gross-Hennersdorf, in Upper Lusatia, in 1739–1741. In 1744, in reply to a call from the Lutheran churches of Pennsylvania, he went to Philadelphia, and was joined from time to time, especially in 1745, by students from Halle. Mühlberg occupied himself more particularly with the congregation at New Providence (now Trappe), though he was practically overseer of all the Lutheran churches from New York to Maryland. In 1748 he organized the first Lutheran synod in America. Mühlberg married in 1745 Anna Maria Weiser, daughter of J. Conrad Weiser, a well-known Indian interpreter, and herself said to have had Indian blood in her veins; by her he had eleven children. Throughout the War of Independence he and his sons (see below) were prominent patriots. He died at Trappe on the 7th of October 1787. The importance of his work in organizing and building up the American Lutheran Church, of which he has been called the Patriarch, can hardly be exaggerated; but his example in preaching in English as well as in German was, unfortunately for the growth of the Lutheran Church, not followed by his immediate successors. He had no sympathy with the Old Lutherans and their strict orthodoxy—on the contrary he was friendly with the Reformed congregations, and with George Whitefield and the Tennents.

See Life and Times by William J. Mann (Philadelphia, 1887).

MÜHLBERG, JOHN PETER GABRIEL (1746–1807), American preacher and soldier, son of H. M. Mühlberg (q.v.), was born at Trappe, Pennsylvania, on the 1st of October 1746. With his two brothers he was educated in Germany. He entered the Lutheran ministry, had charge of churches at New Germantown and Bedminster, New Jersey, and after 1772 of a church in Woodstock, Virginia, and there in 1775 raised the 8th Virginia (German) regiment, of which he was made colonel; in February 1777 he became a brigadier-general in the Continental Army; and in September 1783 was breveted major-general. He took part in the battles of Brandywine, Germantown and Monmouth, and at Yorktown commanded the first brigade of light infantry. After the war he removed to Pennsylvania. He was a member of the Virginia convention of 1776, was vice-president of the supreme executive council of Pennsylvania in 1787–1788, and was a representative in Congress in 1787–1791, in 1793–1795, and in 1799–1801. In 1807 he was elected as a Democratic-Republican to the United States Senate, but immediately resigned to become supervisor of revenue for the district of Pennsylvania. He became collector of the port of Philadelphia in 1803. He was a friend of Thomas Jefferson and of James Monroe.

See Life by Henry A. Mühlburg (Philadelphia, 1849).

His brother, FREDERICK AUGUSTUS CONRAD MÜHLBERG (1750–1801), became his father's assistant in Philadelphia in 1770; was pastor of the Christ (or Swamp) German Lutheran Church of New York City from 1773 to 1776; and in 1777–1779 was assistant to his father at New Hanover. In 1779–1780 he was
a member of the Continental Congress, in 1788–1783 of the Pennsylvania general assembly (then consisting of only one house), and in 1789–1790 of the state constitutional convention. He was president of the Pennsylvania convention which ratified the federal constitution, and was a member in 1789–1797 of the national House of Representatives, of which he was speaker in 1790–1791 and 1793–1795. On the 29th of April 1796, as chairman of the committee of the whole, he cast the deciding vote for the laws necessary to carry out Jay’s treaty.

Another brother, Gotthilf Henry Ernest Muhlenberg (1753–1815), was a prominent Lutheran clergyman, and was pastor of a church in Lancaster, Pennsylvania, from 1779 to his death; but he is best known as a botanist, and published Catalogus plantarum Americae septentrionalis (1813) and Descriptio inferior graminum et plantarum calaminariarum Americae septentrionalis indignarum el circumpolium (1815).

Gotthilf’s son, Henry Augustus Muhlenberg (1782–1844), was pastor of a Lutheran Church in Reading, Pennsylvania, in 1802–1828, was a Democratic representative in Congress in 1830–1838, and was a United States minister to Austria in 1838–1840.

**Muhlenberg, William Augustus** (1796–1877), American philanthropist and Protestant Episcopal clergyman, great-grandson of H. M. Muhlenberg and grandson of F. A. C. Muhlenberg, was born in Philadelphia, Pennsylvania, on the 10th of September 1796. He graduated at the university of Pennsylvania in 1815. In 1817 he was ordained a deacon in the Protestant Episcopal Church, and became assistant to Bishop William White (1748–1836) in the rectorship of Christ Church, St Peter’s and St James’s, Philadelphia. In 1820 he was ordained priest and until 1826 was rector of St James’s Church, Lancaster, Pennsylvania. Largely owing to his efforts Lancaster was the second public school district created in the state. His interest in church music and hymnody prompted his pamphlet of 1823, *A Plea for Christian Hymns*; he drew up for the use of his own parish a collection of Church Poetry (1823); and in 1823 he was appointed by the General Convention a member of the committee on psalms and hymns, whose collection, approved in 1826, contained several of Muhlenberg’s own compositions, including “I would not live alway,” “Shout the glad tidings,” and “Saviour, who thy flock art feeding.” From 1826 to 1845 he was rector of St George’s, Flushing, Long Island, where in 1827 he became head of the Flushing Institute, probably the first Protestant Episcopal “church school” in the United States. He founded a St Paul’s College, to include the institute, but the panic of 1837 and the refusal of a charter by the state legislature brought it to an end; and the property was sold a few years after Muhlenberg left Flushing. From another of his institutions he had purchased a tract of land composed of wood and water; church schools sprang up everywhere; and St Paul’s School, Concord, New Hampshire, and the Groton School in Massachusetts were established in accordance with his ideas. In 1845 he removed to New York City, where in 1846 he became rector of the Church of the Holy Communion, a “free” church built by his sister, Mrs Mary A. Rogers. Here Muhlenberg founded the first American order of Protestant Episcopal deaconesses, the Sisterhood of the Church of the Holy Communion, begun in 1845 and formally organized in 1852. The work of the sisterhood led to Muhlenberg’s establishment of St Luke’s Hospital (opened in 1858), for which his congregation made offerings each St Luke’s Day after 1846. In 1866 he founded on Long Island the Church Industrial Community of St Johnland. He bought 555 acres (mostly wooded), with a shore front of 1 mile on Long Island Sound, near King’s Park, 45 miles from New York. He gave the home for old men (also built in 1866), Sunset Cottage, a home for twelve aged couples, Muhlenberg House, a home for widows, the Fabri Home, the School Cottage (given by Mr and Mrs Cornelius Vanderbilt in 1881) Lawrence House, for babies, a library and village hall, a kindergarten, a school house, and the “mansion.” Dr Muhlenberg’s home at St Johnland and later the home of Sister Anne Ayres, his biographer, during her superintendency of the society.

charitable, and a moderate rent was charged for the cottages. In the St Johnland cemetery is the grave of Dr Muhlenberg, who died on the 8th of April 1877 in St Johnland, New York City. His ideal of the church was that it was missionary and evangelical as well as catholic with formal government and ritual; hence he called himself an “evangelical Catholic” and wrote the *Evangelical Catholic Papers*, which were collected and published by Anne Ayres in 1875–1877.

**Mühlhausen**, a town of Germany, in Prussian Thuringia, on the right bank of the Unstrut, 25 m. N.W. of Gotha by rail. Pop. (1857), 3,533. Mühlhausen is a new and an old town, surrounded by five suburbs, and has many old and churches and towers. The most interesting churches are those of St Michael and of St Blasius, dating respectively from the 14th and the 12th century; the town-hall is also a fine medieval structure. The chief industries are the spinning and weaving of woollen and cotton. Other manufactures include needles, machinery, cigars, soap, hosiery, furniture and shoes. There are also establishments for dyeing, tanning, lime-burning, iron-making, brewing and the preparation of liqueurs.

Mühlhausen is one of the oldest towns in Thuringia, and is said to have been fortified in 925. Its early importance is shown by the grant of privileges made to it by the German King Henry I., and by the fact that there were Jewish settlements in the town. Mühlhausen was the seat of the first Protestant state church in Saxony, and from the time of Luther until the Thirty Years’ War and the Seven Years’ War afterwards reduced Mühlhausen to unimportance. In 1802 it lost its independence and passed to Prussia, in 1807 it was attached to the kingdom of Westphalia, but in 1815 it again became Prussian. The Teutonic Order established itself at Mühlhausen in 1200.

See E. Heydenreich, *Aus der Geschichte der Reichsstadt Mühlhausen* (Halle, 1900); Nebelsieck, *Reformationsgeschichte der Stadt Mühlhausen* (Magdeburg, 1806); Herquet, *Urbandbuch der ehemaligen freien Reichsstadt Mühlhausen* (Halle, 1874); F. Stephan, *Verfassungs geschichte der Reichsstadt Mühlhausen* (Sondershausen, 1886); Jordan, *Chronik der Stadt Mühlhausen* (Mühlhausen, 1900–1906); and Führer durch Mühlhausen und Umgebung (1901).

**Muir, John** (1820–1882), Scottish Orientalist, was born on the 5th of February 1810 in Glasgow, where his father, William Muir (d. 1821), was a merchant. He was educated at the grammar school of Irvine, the university of Glasgow, and the East India Company’s College at Haileybury. He went to India in 1829, and served with distinction in various offices, as assistant secretary to the board of revenue, Allahabad, as collector at Azimgarh, as principal of the Victoria College, Benares, and as civil and session judge at Fatehpur. He encouraged the study of Sanskrit, and furthered schemes for the enlightenment and amelioration of the Hindus. In 1853 he retired and settled in Edinburgh, where he continued his Indian labours. In 1862 he endowed the chair of Sanskrit in the university of Edinburgh, and was the main agent in founding the Shaw fellowship in moral philosophy. He was a fellow of Oxford, LL.D. of Edinburgh and Ph.D. of Bonn, and was one of the first to receive the distinction of C.L.E. He died on the 7th of March 1882.

In 1858 appeared vol. i. of his *Original Sanskrit Texts* (2nd ed., 1868); it was on the origin of caste, an inquiry intended to show that it did not exist in the Vedic age. Vol. ii. (1st ed., 1860; 2nd, 1872) was concerned with the origin and racial affinities of the Hindus, establishing the theory that the Vedas and the whole of the Vedic and later representations of the principal Indian deities, an exhibition of the process by which three gods naturally known to the Vedic hymns became the deities of the former Hindu Trimurti. Vol. iii. (1st ed., 1861; 2nd, 1868) was a full inquiry as to the ideas of their origin, authority and inspiration held by the ancient Vedic and later Indian writers. Vol. iv. (1st ed., 1863; 2nd, 1873) was a comparison of the Vedic with the later representations of the principal Indian deities, an exhibition of the process by which three gods naturally known to the Vedic hymns became the deities of the former Hindu Trimurti. Vol. v. (1870) was on the Vedic mythology. Dr Muir was also the author of a volume of *Medieval Translations from the Sanskrit*, an anonymous work on *Inspiration*, several works in Sanskrit, and many essays in the *Journal of the Royal Asiatic Society* and elsewhere.
MUIR, SIR WILLIAM (1819-1905), Scottish Orientalist, brother of the preceding, was born at Glasgow on the 27th of April 1819. He was educated at Kilmarnock Academy, at Glasgow and Edinburgh Universities, and at Haileybury College, and in 1837 entered the Bengal Civil Service. He served as secretary to the governor of the North-West Provinces, and as a member of the Agra revenue board, and during the Mutiny he was in charge of the intelligence department there. In 1865 he was made foreign secretary to the Indian Government. In 1867 he was knighted (K.C.S.I.), and in 1868 he became lieutenant-governor of the North-West Provinces. In 1873 he was appointed financial member of the Council, and retired in 1876, when he became a member of the Council of India in London. He had always taken an interest in educational matters, and it was chiefly through his exertions that the central college at Allahabad, known as Muir's College, was built and endowed. In 1885 he was elected principal of Edinburgh University in succession to Sir Alexander Grant, and held the post till 1903, when he retired. Sir William Muir was a profound Arabic scholar, and made a careful study of the history of the time of Mahomet and the early caliphate. His chief books are a Life of Mahomet and History of Islam to the Era of the Hegira; Annals of the Early Caliphate; The Caliphate, an abridgment and continuation of the Annals of the Early Caliphate; The Caliphate, a reprint of five essays published at intervals between 1885 and 1887. In 1881 he delivered the Rede lecture at Cambridge on The Early Caliphate and Rise of Islam. He married in 1840 Elizabeth Hunity Wemyss (d. 1897), and had five sons and six daughters; four of his sons served in India, and one of them, Colonel A. N. Muir (d. 1890), was acting resident in Nepal.

MUKADDASI [1] the appellation of Shams ad Din Abu Abdallah Mahomed ibn Ahmad (fl. 967-985), Arabian traveller, author of a Description of the Lands of Islam which is the most original and among the most important of Arabic geographies of the middle ages. His family name was Al Bashari. His paternal grandfather was an architect who constructed many public works in Palestine, especially at Acre, and his mother's family was opulent. His maternal grandfather, a man of artistic and literary tastes, migrated to Jerusalem from Jewry Island. Persia, near the frontier of the desertions rests on an eastern coast for a long series of years. His first pilgrimage was made at the age of twenty (in A.H. 356 = A.D. 967), but his book was not published till A.H. 375 (A.D. 985-986), when he was forty years old.

The two MSS. (at Berlin and Constantinople) represent a later recension (A.H. 378). The book became known in Europe through the copy brought from India by Spranger, and was edited by Professor M. J. de Goeje as the third part of his Bibliotheca Geographorum Arabicorum (Leiden, 1877). See also the English translation (unfinished) by G. S. A. Rankin and R. F. Azzo, in Bibliotheca Indica, New Series, Nos. 899, 952, 1009 (Bengal Asiatic Society, 1897-1901). Mukaddasi's Syrian chapter has been separately translated and edited in English by Guy le Strange (London, Palestine Pilgrims Text Society, 1886); in German by J. Gildemeister in Zeitschrift des deutschen Palästina-Vereins, vol. vii. (1884).

MUKDEN (Chinese Shengking), the capital of Manchuria, on the Hun-ho, 110 m. N.E. of Niuchwang, in 41° 57' N., 123° 38' E., with a population of 300,000. It is a centre of trade and also for missionary enterprise. It was formerly the headquarters of the Manchu dynasty, and their tombs lie within its confines. Mukden is a long town, 1,500 m. by 400 m., and has about 100,000 inhabitants. The suburbs extend a considerable distance from the city and are surrounded by mud walls. In the centre of the town stands a small palace surrounded by an inner wall and roofed with yellow tiles. The boots and pack of Nurhachu, the founder of the present Chinese dynasty, who was a pedlar, are preserved there. Nurhachu's son, the emperor Tien-tsung (1627-1636), built temples to heaven and earth in the neighbourhood of the city in imitation of those at Peking. These are much dilapidated. Four or five miles to the east of the town stands the Fu-ling or "happy tomb" where the remains of Nurhachu rest, the outer gates of which are adorned with a green majolica representation of an imperial dragon. The Emperor K'ien huang (1726-1796) wrote a poem on Mukden, which was translated into French by Père Amiot and attracted the attention of Voltaire.

During the Russo-Japanese War in 1905 some of the heaviest fighting took place before Mukden, what is known as the "battle of Mukden" covering operations from the 19th of February till the Japanese occupied Mukden on the 10th of March and the Russians retreated northward on the 12th.

MUKDISU (Magodoey), a seaport of Italian Somaliland, East Africa, in the 2° 1' N., 45° 24' E. It is built on the sandy coast which separates the Webi Shebell from the sea. The harbour is open. Mukdishu, formerly extensive, is largely in ruins; it consists of two villages, Hamarwini to the south and Shingani to the north. There are some houses in the Moorish style and a mosque among the ruins. The town was taken by the Portuguese in 16th century. The population, about 5100, is mainly composed of descendants of negro slaves known as Abess. There are also Somali, Arab and Hindu settlers. Mukdishu is mentioned as the "itinerant trading port" and as "an important" city. This was in the early part of the 14th century. It was a flourishing port and had many fine mosques when captured by the Portuguese (about 1510). Under Portugal the place fell into decay. It passed in the 17th century into the possession of the imams of Muscat, but in the 18th century became practically independent. It was reconquered by Seyyid Said c. 1830, and on the division of his dominions fell to Zanzibar. In 1892 it was transferred to Italy (see SOMALILAND, Italian). The name of the town is spelt in a great variety of ways, including Madeigasal, whence the name of the island of Madagascar. Alfred Grandier points out that the Portuguese, misled by Marco Polo's description of Mukdishu as an island, fancied they had discovered the land of which he wrote when they touched at Madagascar.

MULA, a town of eastern Spain, in the province of Murcia; on the left bank of the Mula, a small right-hand tributary of the Segura, periodically liable to destructive floods. Pop. (1900), 12,731. The Sierra Espuña rises on the south to a height of nearly 5000 ft. Mula has a small trade in agricultural produce, wine and olive oil. About 4 m. east are two groups of houses known as the Baños de Mula, with warm sulphurous springs of considerable local repute.

MULATTO (Span. and Port. mulato, diminutive of mulo, Lat. mulus, a mule, used as denoting a hybrid origin), a person one of whose parents is of a white race and the other a negro. In Latin America such half-breeds are sometimes called mestizos.

MULBERRY (botanically Morus; nat. ord. Moraceae), a genus of about ten species growing in the temperate regions of the northern hemisphere and in the mountains of the tropics. They are deciduous trees or shrubs with alternate, toothed, often three-lobed leaves and bisexual flowers in catkin-like inflorescences.

The black mulberry (Morus nigra), a native of western Asia, spread westwards in cultivation at an early period; it was cultivated by the Greeks and Romans, and in northern Europe by the 9th and 10th centuries. Up to the 15th century it was extensively grown in Italy for rearing silkworms, but has since been superseded by M. alba. It is now mainly cultivated for its oblong, purplish-black compound fruit—the so-called sorosis, formed from the whole female inflorescence in which the perianth leaves of the single flowers have become fleshy—which is wholesome and palatable if eaten fresh before acetic fermentation has set in. The mulberry succeeds as a standard in the warmer parts of England, especially in sheltered situations, but in the north of England and the less favored parts of Scotland it requires the assistance of a wall. The standard trees require no other pruning or training than an occasional thinning out of the branches, and are generally planted on lawns, to prevent the fruit being damaged when it

1 Al Muakaddas = "the Jerusalemite."
falls. The tree succeeds best in a rich, deep, and somewhat moist loam, but grows well in any good garden ground. It is usually propagated either by cuttings or layers, which latter, if made from the older branches of the tree, come sooner into bearing. Cuttings planted in the spring should consist of well-ripened shoots of the preceding year, with a joint of two-year-old wood at their base, or if planted in autumn should have the shoots well matured, and furnished with a heel of two-year-old wood. The branches and even stout limbs are sometimes employed as cuttings instead of the younger shoots, especially when the object is to obtain a bearing tree quickly.

The branch should be planted deeply in autumn in good soil, and if necessary supported in an upright position by a stake. The most common mode of propagation, however, is by layering the young branches. The mulberry may be grown in pots, and gently forward in an orchard house, and under these conditions the fruit acquires a richness of flavour unknown in the fruit ripened out of doors. If cultivated in this way it requires abundance of water while the fruit is swelling, and also frequent dressings of artificial fertilizers.

The white mulberry (M. alba), so called from its nearly white fruit, is the one mainly employed in sericulture. It is a native of China and has been cultivated from the earliest times in Asia and since the 17th century in Europe, especially in the Mediterranean region. There are many varieties, among which the Philippine mulberry (var. multicaulis) is perhaps most highly esteemed. The Indian species, M. indica (not to be confounded with Morinda citrifolia, a rubiaceous tree, sometimes also called Indian mulberry), is also cultivated for the same purpose.

M. rubra, the North American red mulberry, is the largest of the genus, often reaching a height of 70 ft. It produces dark red berries much inferior in flavour, however, to those of M. nigra.

Broussonetia papyrifera, a member of a closely allied genus, is the paper mulberry, a native of Burma, China and Polynesia, and widely cultivated in Japan, where the bark is used for paper-making. The Tapa-cloth of the South Sea Islands is also made from it. The plant is a shrub or small tree with large mulberry-like lobed or entire hairy leaves. Several forms are cultivated, differing chiefly in the shape of the leaves.

**MULDE**—a river of Germany, a left-bank tributary of the Elbe. It is formed by the confluence, just below Kolditz, of the Zwickauer Mulde, which rising in the Vogtland of Saxony passes Zwickau, Glauchau and Roehlitz, and the Freiberger Mulde, which, rising in the Bohemian Erzgebirge, touches Freiberg, Döblin and Leisnig. The united river flows north to Grimma and thence past Wurzen, Ellenburg and Bitterfeld to Dessau, where it joins the Elbe. The total length of the united river is 75 m.

**MULE** (Lat. mulus), a term not unfrequently applied to the produce of any two creatures of different species, and synonymous with hybrid, but in its usual ordinate application employed to designate the offspring or "cross" between the equine and asinine species. There are two kinds of mule—the Mule proper (Equus asinus, var. γ; Mulus; Fr. Mulet or Grand mulot; Ger. Großer Maulesel), which is the hybrid produce of a male ass with a mare, and the Hinny (Equus asinus, var. δ; Himus; Fr. Bardot or Petit mulet; Ger. Kleiner Maulesel), the offspring of the stallion and female ass. The mule is the more valuable of the two, and to its production the attention of breeders is entirely directed.

In its short thick head, long ears, thin limbs, small narrow hoofs, short mane, absence of chestnuts (horny growths) inside the hocks, and tail destitute of hair at the root the mule is asinine; while in height and body, shape of neck and croup, uniformity of coat, and in teeth it is equine. It has the voice neither of the ass nor of the horse, but emits a feeble hoarse noise. The most common colour of the mule is a brown or bay-brown—bay, or bright bay, or piebald being rare; a chestnut tint is sometimes noticed. It possesses the sobriety, patience, endurance and sure-footedness of the ass, and the vigour, strength and courage of the horse. As a beast of burden it is preferable to the horse, being less impatient under the pressure of heavy weights, while the skin being harder and less sensitive renders it more capable of resisting sun and rain.

The mule has been in use from early times; the inhabitants of Mysia and Paphlagonia are said to have been the first breeders. With the Greeks and Romans, the latter especially, the mule was employed, being employed to draw carriages and carry loads. In modern times it has been largely employed for military transport.

The principal mule countries in Europe are the south of France, Spain, Portugal and Italy, where they are used for pack and draught. The French mules are most numerous on the borders of the Pyrenees, in Gascony, and in Poitou. In Spain mules are used in the Catalan provinces, in the mountainous districts of Andalusia, and in the province of Alicante. Good draught-mules are bred in La Mancha and in the districts on the slopes of the Pyrenees, where they are employed to carry loads. But in Spain, Italy, and some other countries they are also extensively used in carriages; in Spain particularly, where large, fine mules are bred for this purpose, a pair of these animals will often cost more than a pair of horses. The mules of Asia Minor, Syria, Cyprus, Egypt and Algeria, as well as those of the district between the Tigris and the Persian frontier and in North China, are good. In the Punjab provinces of British India many excellent mules are bred, breeding being promoted by the government. Good mules are reared in North and South America, the principal districts for breeding them in the United States being Texas, Missouri, Mississippi, Tennessee, Alabama, Georgia, Arkansas and Kentucky. The Kentucky mules are well shaped and showy, being derived from nearly thoroughbred mares known as Kentucky trotters, while those reared in Missouri are hardly. The Mexican mule, bred by a male ass out of a mustang mare, is also a hardy, strong and useful animal.

France is perhaps the most important mule-raising country in Europe, four centres being more particularly devoted to this kind of industry: Poitou, the mountainous districts of central France, the Pyrenees and Dauphiné. The mules of these different parts differ chiefly in height; those of Poitou are large, powerful, and long in the body, and are mainly exported to the departments of Languedoc and Provence, as well as to Spain, Italy and America; those of Dauphiné are of medium height, with a short, thick body; while those of the centre and the Pyrenees are lighter and smaller, but more active.

Mule-breeding in Poitou is supposed to date from the time of Philip V. of Spain, when the particular breeds of horses and
ases were imported into that region and Gascogne. But there is evidence to show that as early as the 10th century the mules of Poitou were of excellent quality.

**MULGRAVE, EARLDOM OF,** a title dating from 1626, when Edmund Sheffield, 3rd Baron Sheffield of Butterwicke, was created earl of Mulgrave. He was succeeded by his grandson Edmund, the 2nd earl, who was one of the nine true peers who sat in Oliver Cromwell's House of Lords. Edmund's son John, 3rd earl, was created marquess of Normanby in 1694, and duke of Buckingham and Normanby in 1703; but on the death of his son, the 2nd duke, without heirs in 1725, the titles became extinct. The 2nd duke devised the estates of the Sheffield family to his mother Catherine, a natural daughter of James II., who had married as her first husband the 3rd earl of Annesley, by whom she had a daughter Catherine, who married William Phips and had a son Constantine Phips. The latter succeeded to the estate of Mulgrave in Yorkshire in 1743 on the death of his grandmother, and in 1767 he was created Baron Mulgrave of New Ross in the peerage of Ireland. His son was created a peer of Great Britain in 1790 with the title of Baron Mulgrave of Mulgrave; and the latter's brother Henry, the next in succession, who was secretary of state for foreign affairs in 1801 and her husband, in 1812, was created Viscount Normanby and earl of Mulgrave in 1812. The 2nd earl of this creation, who like his father held several high cabinet offices, was advanced in the peerage at the coronation of Queen Victoria, being created marquess of Normanby in 1838.

**MULHAUSEN** (Fr. Mulhouse), a town of Germany, in Upper Alsace, on the III, an affluent of the Rhine, and the Rhine-Rhone canal, about 56 m. S. of Strassburg and 21 m. N.W. of Basel by rail. The old town, surrounded by arms of the Ill, has narrow and irregular streets, while to the south, on the canal, lie the handsome villas and promenades of the new town. Most of the older buildings have made way for factories, so that the town-hall, dating from 1531, is an almost solitary witness to the town's medieval prosperity. The most important interest of Mulhausen centres in the making of cotton goods. This industry was introduced in 1746, and has since prospered in the hands of several wealthy families which are closely connected by intermarriage, and lend each other support. A large proportion of the inhabitants of the town and the neighbourhood is engaged in the manufacture of cotton goods, and other textile manufactures, the products of which are exported to all parts of the world. The manufactures of machinery, especially locomotives and railway plant, chemicals, and hardware are also important. A noteworthy feature is the attention paid by the manufacturers to the well-being of their workpeople. In 1855, Johann Heinrich Dollfus (1800-1887), mayor of the town, founded the "artisans' town" (cité ouvrière) to the north-east of the old town, consisting of about 1200 model dwellings with public bath-, wash- and bake-houses, and library. The houses were let on a system by which the occupant became the owner after the payment of a certain number of instalments. Of recent years, however, the operatives have moved into the suburbs, leaving the model houses of the "artisans' town" to small tradesmen. A "société industrielle" for the encouragement of original discovery and invention among the workmen has existed since 1825, and there are various benevolent societies. Mulhausen carries on an active trade in grain, wine, colonial produce and timber, which is facilitated by its river harbour. After the annexation of Alsace to Germany in 1871 the French sympathies of the inhabitants were shown by the extraordinary decrease in their number. The population has since increased, amounting in 1905 to 94,514, of whom about two-thirds are Roman Catholics.

Mentioned as early as 777, Mulhausen was raised to the rank of a free town of the empire in 1108, and received very extensive privileges from Rudolph of Hapsburg in 1273. It suffered considerably in the various wars of the middle ages, but generally managed to maintain its independence. In 1466 it formed an alliance with the Swiss, and this became a permanent union in 1515. By the peace of Westphalia (1648) it was recognized as an independent ally of the Swiss League. In 1579 it sought incorporation with France from motives of commercial policy, and in 1871 it passed to Germany.

**MÜLHEIM-AM-RHEIN,** a town of Germany, in the Prussian Rhine province, on the right bank of the Rhine, 2 m. below Cologne, of which it is practically a suburb, and on the main lines of railway Cologne-Düsseldorf and Cologne-Erleberfeld. Pop. (1905), 50,807. There are important manufactures of silk, ribbons, velvet, sailcloth, tobacco, vinegar, yarn and chemicals, in addition to rolling-mills, boiler works, telegraph works, breweries, tanneries and a ship-building yard. Mulheim also carries on a brisk trade by rail and river.

Of ancient foundation, Mulheim received municipal rights in 1322. Its industrial prosperity is in great part due to the influx of Protestants expelled from Cologne at the beginning of the 17th century. In 1784 the town suffered severely from an inundation caused by the rapid breaking-up of the ice on the Upper Rhine.

**MÜLHEIM-AN-DER-RUHR,** a town of Germany, in the Prussian Rhine province, on the Ruhr, an affluent of the Rhine, about 7 m. W. from Essen and at the intersection of several railways. Pop. (1905), 93,598. It has a parish church dating from the 12th century. Like most of the towns in this district, Mülheim finds its chief industry in iron-working, and contains numerous blast-furnaces, rolling-mills, foundries and engine-works; it also carries on manufactures of leather, wool, cotton, calico, tobacco, paper, beer, and other miscellaneous goods. An enormous traffic, by river and rail, is carried on in coal, and there is also a considerable trade in timber and colonial produce. In the neighbourhood are important sandstone quarries, glass-works, and a carpet manufactory. Mülheim was formerly included in the duchy of Berg, and became a town in 1508. In 1815 it passed to Prussia.

**MULJI, KURSENDAS** (1832—1875), Indian journalist and social reformer, was born on the 25th of July 1832, of a family belonging to the Bhatia or trading caste of western India. Being repudiated by his family on account of his views on widow remarriage, he became a vernacular schoolmaster, and started a weekly paper in Gujarati called *The Satya Prakash.* In this he attacked the immorality of the Maharajas or hereditary high priests of the Vallabhaacharya sect of Vaishnavism to which the Bhatias belong. In a suit for libel brought against him in the High Court at Bombay in 1862, he won a victory on the main issue. After a visit to England on business in connexion with the cotton trade, which was not successful and brought on him excommunication from his caste, he was appointed in 1874 to administer a native state in Kathiawar during the minority of the chief; and there he died in August 1875.

See *History of the Sect of Maharajas or Vallabhaacharyas of Western India* (1865).

**MULL,** the largest island of the Inner Hebrides, Argyllshire, Scotland. Pop. (1901), 4334. It is bounded on the W. and S. by the Atlantic, on the N. and E. by the Sound of Mull, and on the E. and S.E. by the Firth of Lorne. It has an area of about 367 sq. m., its greatest length being 27 m. and its greatest breadth 15 m. It is indented, the principal sea-lochs being Loch Mingary, Loch Cuan, Loch Tua, Loch na Keal, Loch Scridain, Loch Buie, Loch Spelve and Loch Don. Among several freshwater lakes Loch Frisa, Loch Ba and Loch Uig are thechief. The principal mountains are Ben More (3185 ft.), Ben Buy (2354 ft.) and Ben Creach (2289 ft.). In the basaltic cliffs near Carails are numerous arches and caverns. The prevailing rocks are igneous (generally basaltic, gabbro in the mountains in the south-east, granite in the Ross). The valleys are filled up with lava flows and volcanic ashes of Miocene age. At a few places there are gneissose rocks, chalk, sandstone licks and quartz porphyry. Sheep and cattle are raised, and barley, oats and potatoes grown. Owing to the damp climate the island is better suited for grazing than for cultivation.
Granite and freestone are quarried. Ben More deer forest and the excellent fishing and shooting attract many sportsmen. There are several ancient castles, the principal being those of Duart and Aros. Close to the former is a lighthouse erected in memory of William Black, the novelist (d. 1858). About midway between Mull and Lismore is the Lady Rock, visible at low water, on which, in 1523, Lachlan Maclean of Duart exposed his wife, a daughter of the second earl of Argyll, expecting that she would be drowned by the flowing tide. She was, however, saved by her clansfolk and her husband was afterwards slain by her brother. Joanna Baillie (1762–1851) made the incident the leading theme of her drama of The Family Legend. TObErmorX ("the Well of Mary," so called from a spring of local celebrity) is the only town (pop. 1175). It is placed on a pretty bay, the houses standing on tree-clad heights. It was founded in 1788 as a station for fishing-boats, and the herring fishery is still of some consequence. It has regular communication by steamer with Stornoway, Oban and Glasgow. Off the north-western shore of Mull, separated by a narrow strait, lies the isle of Ulva, 1/2 m. long and 2 m. broad, whose inhabitants are mostly engaged in fishing and kelp-gathering. Close to Ulva, and practically one with it at low tide, is the isle of Gometra, about 1/2 m. long and 2 m. broad, the people of which are chiefly occupied with fishing. Liltte CoLSOnSay lies about 2 m. south of Ulva. Farther west is the small group of the Treslinsh Isles.

MULL (1) A soft plain muslin exported largely from England to India, &c., and used also in some qualities for summer dresses in the home trade. The name is an abbreviation of the Hindn musilm. (2) A word, derived from the same root as seen in "meal" and "mill," meaning that which is ground or reduced in other ways to powder or small particles. Thus a sniff-box is in Scotland called a "mull," from the early machines in which the tobacco was ground. Large snuff-mulls, which remained stationary on a table as opposed to the small portable boxes of the form of a man's head ornamented in silver. Possibly from the ground or grated spices with which ale or wine is flavoured when heated, comes the expression "mulled," as applied to such a beverage. The colloquial expression "to make a mull," i.e. to muddle or make a failure of something, also perhaps connected with "to mull," to reduce to powder. (3) The Scots word "mull," meaning a promontory or headland, as the Mull of Galloway, the Mull of Kintyre, represents the Gaelic maol, cf. Icelandic möl in the same sense; this may be the same as mólí, snout, cf. Ger. Maul.

MULLAH (Arabic maqul, a term which originally expresses the legal bond connecting a former owner with his manumitted slave, both patron and client being called maqul, and thus suggests the idea of patronage), in Mahomedan countries, a learned man, a teacher, a doctor of the law, in India the term is applied to the man who reads the Koran, and in the Mussulman schoolmaster. In countries like Afghanistan the mullahs exert an influence over the populace which sometimes rivals that of the amir himself, and they have been responsible for many disturbances in Kabul. Among the democratic tribes of the north-west frontier of India they almost take the place of a secular chief. In the Indian frontier risings of 1857–9 the "mad mullah" of Swat led the attack upon the Malakand, while the Hadda mullah was largely responsible for the risings amongst the Mohmands, Afridis and Orakzais. The leader of the risings in Sollmand in 1899–1901 was similarly known as the "mad mullah."

MÜLLER, FERDINAND VON, BARON (1825–1859), German botanist and explorer, was born at Rostock on the 30th of June 1825, and was educated, after the early death of his parents, in Schleswig. He studied the flora of Schleswig and Holstein from 1840 to 1847, when he emigrated to South Australia and travelled through the colony from 1848 to 1852, discovering and describing a large number of plants previously unknown. In 1852 he was appointed government botanist for Victoria, and examined its flora, and especially the Alpine vegetation of Australia, which was previously unknown. Then, as phytographic naturalist, he joined the expedition sent out under Augustus Gregory by the duke of Newcastle, secretary of state for the colonies. He explored the river Victoria and other portions of North Australia, was one of the four who reached Termination Lake in 1856, and accompanied Gregory's expedition overland to Moreton Bay. From 1857 to 1873 he was director of the Botanical Gardens, Melbourne, and not only introduced many plants into Victoria, but made the excellent qualities of the blue gum tree (Eucalyptus globulus) known all over the world, and succeeded in introducing it into the south of Europe, North and South Africa, California, and the extra-tropical portions of South America. For these services he was decorated by many foreign countries, including France, Spain, Denmark and Portugal; was created K.C.M.G. in 1879, baron of the kingdom of Württemberg in 1871, and F.R.S. in 1881. He published eleven volumes of Fragmenta phytographica Australis (1862–1881), two volumes of the Plants of Victoria (1862–1871), and other books on the Eucalyptus, Myopoe- racae, Acacias, and Salisoleae, all profusely illustrated. He also co-operated in the production of G. Bentham's Flora Austra- liensis. He took a leading part in promoting Australian exploration, especially the Burke and Wills expedition, which was the first to cross the continent, and in the various attempts to unravel the mystery which attended the fate of his fellow-countryman Ludwig Leichhardt (1813–1848). He died at Melbourne on the 9th of October 1896.

MÜLLER, FRIEDRICH (1749–1825), German poet, dramatist and painter, usually known as Maler (i.e. painter) Müller, was born at Kreuznach on the 13th of January 1749. He studied painting at Zweibrücken, and in 1774–1775 settled in Mannheim, where in 1777 he was appointed court painter. In 1778 he was enabled by a public subscription to visit Italy, which remained his home for the rest of his life. In 1780 he became a Roman Catholic. He was unfavourably influenced by the study of Italian models, and gave himself up to the study of the history of art; his services as cicerone were in special demand among German visitors to Rome. Before he left Mannheim he had tried his hand at literature, under the influence of the Sturm und Drang movement. A lyric drama, Niobe (1778), attracted little attention; but Fausts Leben drosamisirt (1778) appealed to the turbulent spirit of the age, and Golo und Genoveva (begun in 1776, but not published till 1811) was an excellent imitation of Goethe's Götz von Berlichingen. He struck out a more independent path in his idyls, notably Die Schafschur (1775) and Das Nusskern (1811), in which, emancipating himself from the artificiality of Gessner, he reproduced scenes—not without a touch of satire—from the German peasant life of his day. He died at Rome on the 23rd of April 1825.

Maler Müller's Werke appeared in 3 vols. (1811–1825); in 1868 H. Hettner published two volumes of Dichtungen von Maler Müller, which contain most of his writings. Gedichte von Maler Friedrich Müller; eine Nachleue zu dessen Werken appeared in 1873, and his Fausts Leben was reprinted by B. Seuffert in 1881. See A. Sauger, "Stirrner und Dränger," vol. iii. (Kürschner's Deutsche Nationalliteratur, vol. 81, 1883); and B. Seuffert, Maler Müller (1877).

MÜLLER, GEORGE (1805–1898), English preacher and philanthropist, was born near Halberstadt, Germany, on the 27th of September 1805, the son of an exciseman. He subsequently became a naturalized British subject. Educated in Germany, he resolved in 1836 to devote himself to missionary work, and in 1838 went to London to prepare for an appointment offered him by the Society for promoting Christianity among the Jews. In 1839 however he gave up the idea of missionary work, and became minister of a small congregation at Teignmouth, Devonshire. He contended that the temporal as well as the spiritual needs of life could be supplied by prayer, and on this principle abolished pew rents and refused to take a fixed salary. After two years at Teignmouth, he moved to Bristol, where he spent the rest of his life. He devoted himself particularly to the care of orphan children. He began by taking a few under his charge, but in course of time their number increased to 2000, settled in five large houses erected for the
MÜLLER, J. P.—MÜLLER, J.

purpose at Ashley Down, near Bristol. The money required for the carrying on of this work was voluntarily contributed, mainly as a result of the wide circulation of Müller's narrative The Lord's Dealings with George Müller. When he was over seventy he started on a preaching mission, which lasted nearly seventeen years and included Europe, America, India, Australia and China. He died at Bristol on the 10th of March 1898.

See A. T. Pierson, George Müller of Bristol (1893).

MÜLLER, JOHANNES PETER (1807—1858), German physiologist and comparative anatomist, was born at Coblenz on the 14th of July 1801. In 1820 he entered Bonn University, where he became privatdocent in 1824, extraordinary professor of physiology in 1826, and ordinary professor in 1833. In 1840 he was appointed to the university of Berlin, where he filled the chair of anatomy and physiology with great distinction until his death on the 28th of April 1858. Müller made numerous researches in various departments of physiology, and in particular he extended knowledge as to the mechanism of voice, speech and hearing, and as to the chemical and physical properties of lymph, chyle, and blood. The appearance of his Handbuch der Physiologie des Menschen between 1833 and 1840 (translated into English by Dr William Baly, and published in London in 1842) marked the beginning of a new period in the study of physiology. In it, for the first time, the results of human and comparative anatomy, as well as of chemistry and other departments of physical science, were brought to bear on the investigation of physiological problems. The most important portion of the work was that dealing with nervous action and the mechanism of the senses. Here he stated the principle, not before recognized, that the kind of sensation following stimulation of a sensory nerve does not depend on the mode of stimulation but upon the nature of the sense-organ. Thus light, pressure, or mechanical stimulation acting on the retina and optic nerve invariably produces luminous impressions. This he termed the law of the specific energy of sense-substances. In the later part of his life he chiefly devoted himself to comparative anatomy. Fishes and marine invertebrata were his favourite subjects. Müller numbered such distinguished physiologists as H. von Helmholtz, E. Du Bois Reymond and K. F. W. Ludwig among his pupils.

In addition to his Handbuch der Physiologie, his publications include Zur vergleichenden Physiologie des Geschlechts (1826); Über die plasmatischen Geschichterscheinungen (1826); Bildungsgeschichte der Genitalien (1830), in which he traced the development of the Müllerian duct; De glandulorum secretarium structura (1830); Vergleichende Anatomie der Myxinoidea (1834—1843); Systematische Beiträge zur Anatomie der Aderen (1842) with F. H. Troschel; and Horse ichthologie (1845—1849) with the same. After the death of J. F. Meckel (1781—1833) he edited the Archiv für Anatomie und Physiologie.

MÜLLER, JOHANNES VON (1752—1809), Swiss historian, was born on the 3rd of January 1752 at Neunkirch, near Schaffhausen, where his father was pastor. In 1760 the family removed to Schaffhausen. In his youth his maternal grandfather, Schoop (d. 1757), roused in him an interest in the history of his country. At the age of eight he is said to have written a history of Schaffhausen, and at eleven he knew the names and dates of all the kings of the four great monarchies. His admiration for historical studies was further stimulated by Schlozer, when Müller went (1760) to the university of Göttingen, nominally to study theology. In July 1772 he undertook a sketch of Swiss history (no detailed history of Switzerland having so far been written) for a publisher of Halle, but his theological studies and the preparation of a Latin dissertation on the Bellum cimbrium (publ. in 1772) prevented much progress. In April 1772 he passed his theological examination, and soon after became professor of Greek at the Collegium Humanitatis. Early in 1774, on the advice of his friend Charles Victor de Bonstetten, he gave up this post and became tutor in the Tronchin family at Geneva. But in 1775 he resigned this position also, and passed his time with various friends in Geneva and Vaud, engaged in carrying his historical scheme into effect. Having accumulated much material, he began the actual composition of his work in the spring of 1776, and the printing in the summer of 1777. But difficulties arose with the censor, and matters came to a standstill. In 1778 Müller delivered a brilliant set of lectures on general history, which were not published till 1839 under the title of Vierundzwanzig Bücher allgemeiner Geschichte. In 1780 the first volume (extending to 1788) of his Geschichten der Schweizer appeared, nominally at Boston (to avoid the censor), though really at Bern; and it was well received. In 1781 he published at Berlin, in French, his Essais Historiques. He was on his way back to Switzerland when the magistrate of Herzog Cassel named him professor of history. He stayed at Cassel till 1783, publishing in that year Reisen der Pütste, a book wherein certain leanings towards Romanism are visible. On his return to Geneva (1783) he accepted the post of reader to the brother of his old patron, Tronchin, and occupied himself with remodelling his published work of 1780. In order to improve his financial position, he accepted early in 1786 the post of librarian to the elector-archbishop of Mainz, who bestowed many important offices upon him and obtained his elevation to nobility from the emperor in 1791. In June 1786 he issued vol. i. (reaching to 1412) and two years later vol. ii. (to 1430) of the definitive form of his Swiss history, which was received with great praise. In 1787 he issued an important political tract, Zur Darstellung des Fürstenbundes. But in October 1792 Mainz was taken by the French, so that Müller had to seek for another post. In February 1793 he entered the service of the emperor as an imperial aulic councillor. At Vienna he spent many years, becoming chief librarian of the imperial library in 1806, and in 1815 he was raised to the nobility (1443) of his Swiss history. In 1804 he became historiographer, war councillor, and member of the Academy at Berlin. In 1805 vol. iv. (to 1475) appeared. But in 1806 he became strongly inclined towards Napoleon, by whom he was received in audience (Nov. 1806), and from whom he accepted (end of 1807) the office of secretary of state for the kingdom of Westphalia, exchanging this position early in 1808 for the posts of privy councillor and general director of public instruction. At the end of 1808 he published vol. v. (to 1489) of his great work. He died at Cassel on the 29th of May 1809. His Swiss History now possesses a literary value only, but it was an excellent work in every way for the 18th century.

Müller's works were published under the care of his brother at Tübingen, in 27 vols. (1810—1821), and re-issued, in 40 vols., at Strasbourg (1822—1833). The Swiss History was published for Berlin, Geneva, Cassel and Zürich, in 15 vols. (1824—1833), with continuations by Glutz-Blöheim (to 1517), Hottinger (to 1531), Vulliemin (to 1712), and Monnard (1715). A French translation of the German edition as well as an English translation of the published Passau and Paris papers appeared in London.

See the biographies by Heeren (1809), Döring (1835) and Monnard (1839); also in G. v. Wyss's Geschichte der Historiographie in der Schweiz (Zürich, 1895), pp. 305—311, and in the Festchrift der Stadt Schaffhausen (Schaffhausen, 1891), p. vii. pp. 83—99. F. Schwarz's pamphlet, J. von Müller und seine Schweizerschicht (Bâle, 1884), traces the genesis of the History. Müller's letters to Füsslin (1777—1807) were issued at Zürich (1812), and those to Ch. Bonnet, d. c., at Stuttgart (1835). Those addressed to him by various friends were published by Maurer-Constant, in 6 vols. (Schaffhausen, 1839—1840); and those written to him (1789—1809) by his brother, J. G. Müller, appeared, under the editorship of E. Haug, at Frauenfeld, in 2 vols. (1891—1892).

MÜLLER, JULIUS (1801—1878), German Protestant theologian, was born at Bregen on the 11th of April 1801. He studied at Breslau, Göttingen and Berlin, first law, then theology; and in 1835 became professor ordinarius of theology at Halle (1835—1846). In the latter year he took the charge of the Parochialkirche, Kirchweg, and two years later founded and edited (1850—1865) the Zeitschrift für christlich-soziale Wissenschaft und christliches Leben. He died at Halle on the 27th of September 1878. A disciple of Neander and friend of Richard Rothe, Müller bitterly opposed the philosophy of Hegel and the criticism of F. C. Baur. His book, Über den Gegensatz des Protestantismus und des Katholizismus (1833), called forth a reply from Baur, and he was one of those who attacked D. Strauss's Leben von Jesus. In 1846 he had been invited to attend the General Evangelical Synod at Berlin. Here he supported the Consensus-Union, and afterwards defended
MÜLLER, K. O.—MÜLLER, W. J.

himself in the pamphlets *Die erste Generalsynode der evang. Landeskirche Preussens* (1847) and *Die evangelische Union, ihr Wesen und göttliches Recht* (1854). His chief work, however, was *Die christliche Lehre der Sünde* (2 vols., 1839; 5th ed., 1867; Eng. trans. from 5th ed., in which he carried scholasticism as far as *to revive the ancient Gnostic theory of the fall of man* for all time, a theory which found no favour amongst his theological contemporaries (Otto Pfleger, J. H. M. Muller).

Müller's other works include *Dogmat. Abhandlungen* (1870), and *Das christliche Leben* (3rd ed., 1847). See M. Kahler, Julius Müller (1878); L. Schultz, Julius Müller (1879) and Julius Müller als Ethiker (1895).

MÜLLER, KARL OTFRIED (1797-1840), German scholar, was born at Bries in Silesia on the 28th of August 1797. He was educated partly in Breslau, partly in Berlin, where his enthusiasm for the study of Greek literature, art and history was fostered by the influence of Büsch. In 1817, after the publication of his first work, *Ager Academiarum Liber*, he received an appointment at the Magdaleneum in Breslau; and in 1819 he was made adjunct professor of ancient literature in the university of Göttingen, his subject being the archaeology and history of ancient art. His aim was to form a vivid conception of Greek life as a whole; and his books and lectures marked an epoch in the development of Hellenic studies. Müller's position at Göttingen was rendered unpleasant by the political troubles which followed the accession of Ernest Augustus (duke of Cumberland) to the throne of Hanover in 1837, he applied for permission to travel; and in 1839 he left Germany. In April of the following year he reached Greece, having spent the winter in Italy. He investigated the remains of ancient Athens, visited many places of interest in Peloponnese, and finally went to Delphi, where he began excavations. He was attacked by intermittent fever, of which he died at Athens on the 1st of August 1840.

Among his historical works the foremost place belongs to his *Geschichten hellenischer Stämme und Städte: Orchomenos und die Minyer* (1820), and *Die Dorier* (1824; Eng. trans. by H. Tufnell and Cornwell Lewis, 1830, including the essay *Über die Make- donier*, on the settlements, origin and early history of the Macedonians). He introduced a new standard of accuracy in the cartography of ancient Greece. In 1828 he published *Die Etrusker*, a treatise on Etruscan antiquities. His *Prolegomena zu einer wissenschaftlichen Mythologie* (1825; Eng. trans., J. Leitch, 1844), in which he avoided the extreme views of G. F. Creuzer and C. A. Lobbeck, prepared the way for the scientific investigation of myths; while the study of ancient art was promoted by his *Handbuch der Archäologie der Kuns* (1830; Eng. trans., J. Leitch, 1847), and *Denkmäler der altdeutschen Kunst* (1832), which he wrote in association with C. Oesterley. In 1840 appeared in England his *History of the Literature of Ancient Greece; the original German work from which... had been translated being issued in Germany in 1841* (4th ed. by E. Heitz, 1882). Chapters i.—xxii. were translated by Sir George Cornewall Lewis; chapters xxiii.—xxvi. by J. W. Donaldson, who carried the work down to the taking of Constantinople by the Turks. It is still one of the best books on the subject. Müller also published an admirable translation of the *Eumenides of Aeschylus* with introductory essays (1833), and new editions of *Varro* (1833) and *Festuc* (1839).

MÜLLER, LUCIAN (1836-1898), German scholar, was born at Merseburg in Prussian Saxony on the 17th of March 1836. Having studied at Berlin and Halle, he resided for five years in Holland, where he collected the materials for his *Geschichte der klassischen Philologie in den Niederlanden* (1869). Unable to obtain a university appointment in Germany, he accepted (1870) the professorship of Latin at the Imperial Historico-Philological Institute in St Petersburg. There he died on the 24th of April 1898. Müller was a disciple of the methods of Heitz and Leichmann. His *Die hebräische Poesie* (1861—2nd ed., 1894) represents a landmark in the investigation of the metrical system of the Roman poets (the dramatists of Greece and Rome); and his *Metricon der Griechen und Römer* (2nd ed., 1885) is an excellent piece in a small compass (Eng. trans. by S. B. Platenor, Boston, Mass., 1882).

His other chief publications were: *C. Lucilius satirarum reliquiae* (1872), including the fragments of Accius and Sueius; *Leben und Werke des Gaius Lucilius* (1876); *suppl. Luciliana*, 1884; *ed. Horace* (1869; 3rd ed., 1897); *Quintus Horatius Flaccus, eine literarhistorische Darstellung* (1892); *O. Ennius carminum reliquiae* (1884); *Liv. Andromice et Cn. Novi fabularum reliquiae* (1889); *Der sarturische Vers und seine Denkmäler* (1888); *Novi Marcelli componenda doctrina* (1889); *De Facundis fabulis* (1891); *De Acci fabulis disputatio* (1890).

MÜLLER, WMILHELM (1794—1827), German lyric poet, was born at Dessau on the 7th of October 1794, the son of a shoemaker. He was educated at the gymnasium of his native town and at the university of Berlin, where he devoted himself to philological and historical studies. In 1813—1814 he took part, as a volunteer, in the national rising against Napoleon. In 1817 he visited Italy, and in 1820 published his impressions in *Rom, Römer und Römerinnen*. In 1818 he was appointed teacher of classics in the Dessau school, and in 1820 librarian to the duval library. He died at Dessau on the 30th of September 1827. Müller's earliest lyrics are contained in a volume of poems, *Bundesbluten*, by several friends, which was published in 1816. His literary reputation was made by the *Gedichte aus den hinterlassenen Papieren* (2 vols., 1821—1824), and the *Lieder der Griechen* (1821—1824). The latter collection was Germany's chief tribute of sympathy to the Greeks in their struggle against the Turkish yoke, a theme which inspired many poets of the time. Two volumes of *Neugriechische Volkslieder* and *Lyrische Reisen* and *epigrammatische Späazergänge*, followed in 1825 and 1827. Müller also wrote a book on the *Homeriche Vorschule* (1824; 2nd ed., 1836), translated Marlowe's *Faustus*, and edited a *Bibliothek der Dichtungen des 17. Jahrhunderts* (1822—1877; 10 vols.). His poetic genius was kindled to that of the composer Schubert, who set many of his lyrics to music.

Wilhelm Müller's *Gedichte* were first collected in 1827 (4th ed., 1834; 5th ed., 1847), and are edited by his son, F. Max Müller (1868); there are also numerous more recent editions, notably one in Reclam's Universal-bibliothek (1894); critical edition by J. T. Hatfield (1906). Müller's *Verhöfene Schriften* were edited with a biography by G. Schwab (3 vols., 1841) and an *essay* by F. Max Müller (1868). *G. Curtius, Die homerische Geschichts- und-weise*; O. Franck, *"Zur Biographie des Dichters W. Müller"* (Mitteilungen des Vereins für anhaltische Geschichte, 1887); J. T. Hatfield, "W. Müller's unveröffentlichtes Tagebuch und sein ungedrucktes Briefe* (Deutsche Rundschau, 1907).

MÜLLER, WILLIAM JAMES (1812—1845), English landscape and figure painter, was born at Bristol on the 8th of June 1812, his father, a Prussian, being curator of the museum. He first studied painting under J. B. Pyne. His early subjects deal mainly with the scenery of Gloucestershire and Wales, and he learned much from his study of Claude, Ruysdael, and earlier landscape-painters. In 1833 he figured for the first time in the Royal Academy with his "*Destruction of Old London Bridge—Morning," and next year he made a tour through France, Switzerland and Italy. Four years later he visited Athens, extending his travels to Egypt, and in the sketches executed during this period and the paintings produced from them his power and individuality are apparent. Shortly after his return he left Bristol and settled in London, where he exhibited regularly. In 1840 he again visited France, where he executed a series of sketches of Renaissance architecture, twenty-five of which were engraved by Muller in 1841, in a folio entitled *The Age of Francis I. of France*. In 1843 he accompanied, at his own request and his own charges, the government...
expedition to Lycia, where he made a number of masterly sketches. He died at Bristol on the 8th of September 1845.

The print room of the British Museum possesses, through the bequest of Mr John Henderson, a rich collection of Muller's sketches. A biography by N. Neal Solly was published in 1875.

**MULLET**, the name of two different kinds of fishes, distinguished as red mullets and grey mullets.

Red mullets (genus *Mullus*, the name given by the ancient Romans) are marine fishes, with two short dorsal fins remote from each other: the first is composed of feeble spines, the second of branched rays; the anal fin is similar to the second dorsal. The body is covered with large thin scales. The form of the head is peculiar; its anterior profile slopes downwards to the small mouth, which has very small and feeble teeth, and from which two cylindrical barbels are suspended. These organs of touch are generally laid backwards and hidden in a groove between the branches of the lower jaw, but can be erected and called into action independently. About forty different species of red mullets are known, chiefly from the tropical and subtropical parts of the Indo-Pacific ocean. In European waters two forms are known which have received different specific names, *Mullus surmuletus* and *Mullus barbatus*. The former in the Mediterranean, the general red colour has three to five bright yellow bands along the sides from head to tail; these are absent in the other form. It has been proved that this is not a sexual difference, the two forms are varieties or species. The striped form is usually found on the coasts of England, where the plain form is rare or absent. In the Mediterranean both kinds occur, but it is probable that the striped form, which is larger, is more common in the Atlantic and the plain form in Mediterranean and southern waters.

Red mullets do not attain any considerable size, the largest of the tropical species weighing only two or three pounds. They are ground-feeders, evidently using their barbels in discovering their food, which consists of crustacea, worms, and, in the larger species, of small fishes; that they feed on putrid flesh is not borne out by the evidence drawn from their feeble jaws and dentition, but it is probable that they are attracted to a decomposing body by the presence of the small crustaceans which feast upon it. Although the colours of these fishes are bright, they are sometimes a very pale resemblance; a large number of tropical species exhibit ornamentations in the form of black spots or bands. In many, as also in the European species, red colour prevails, and its preservation after death is considered to enhance the fitness of the fish for the table, and consequently its market value. To produce the intensity of this red colour, fishermen scale the red mullet immediately before its death, a process by which the red pigment cells or chromatophores are excited to expand; fishes which are allowed to die in the water show little red, and therefore red mullets caught by the trawl are less valuable than those obtained in a trammel-net, by which the majority are secured alive. All the species are esteemed as food; but none equals the European species, which was held in exaggerated esteem by the gourmards of Rome. They exhibited the living fish and allowed them to die at the table immediately before they were consigned to the cook; they kept them in large reservoirs until they were wanted, and paid fabulous prices for fishes somewhat above the average size. Little is known about the habits of red mullets; during winter they retire into deep water, late in spring and during summer they approach the coasts and enter even brackish water, but the state of their sexual organs shows that they do not come towards the shore to breed. At Naples they spawn from May to August, and their ova are buoyant and transparent. In June, July and August the young are about an inch long, and already furnished with the two barbels.

The grey mullets form a widely different and distinct family, *Mugilidae*. They are not exclusively marine, but enter brackish water, live always close to the shore, and some of the tropical forms inhabit the pure fresh water of streams and rivulets, without, however, penetrating far inland. Their body is elegantly formed, wedge-shaped, and covered with scales of moderate size, firmly adherent to the skin. The two short dorsal fins are remote from each other, and the anterior is composed of four stiff spines. The anal fin is similar to the second dorsal; the caudal fin strong and bilobed. The form of the snout is peculiar; the mouth narrow, transverse in the true *Mugil*, and without, or with but feeble, teeth. About seventy different species are known, from almost every coast of the temperate and tropical zones; they swim in small schools and are abundant wherever they occur. Two species are found on the British coasts—*Mugil capito* and *Mugil chelo*, the first being the more common. Some of the fresh-water grey mullets of the tropics, especially those of the West Indian and Indo-Pacific islands, have the mouth more lateral or have distinct though minute teeth; they therefore have been formed into separate genera, *Agonostoma* and *Myxus*.

Grey mullets, at least some of the species, grow to a weight of 10 or 12 lb; but the fish which usually come into the market rarely exceed half that weight. Those in which distinct teeth are developed feed principally on small aquatic animals, whilst the diet of those without teeth consists of animalculae or minute organic substances mixed with the mud or sand which they swallow in large quantities; and also coniferous growths to which they are attached and adhere. To prevent the gills from being clogged by sand or mud, a peculiar apparatus separates these organs from the pharynx. Each branchial arch is provided on each side, in its whole length, with a series of closely-set gill-rakers, each series fitting into the series of the adjoining arch; they constitute together a sieve permitting the passage of the water, while retaining other substances in the cavity destined for mastication. The structure of the intestinal tract is also adapted to the diet of these fishes. One portion of the stomach is globular and surrounded by a thick mass of muscles, the cavity being small and coated with a tough epithelium. This structure reminds us of the stomach of birds, in which it also serves for the trituration of hard substances. The intestine itself is six or seven times as long as the fish. Grey mullets are plainly coloured, generally greenish on the upper parts and more or less silvery on the side. They are wholesome food, well flavoured when taken out of clean water. In the fish-farms of western Italy grey mullets are among the principal fish cultivated. (J. T. C.)

**MULLIGATAWNY**, the name, derived from the Tamil *milagu-tannir* (*i.e.* pepper water), given to a favourite hot East Indian soup, made with curry-powder and otherwise highly seasoned, and served usually with rice.

**MULLINGAR**, a market-town, and the county town of county Westmeath, Ireland, near the river Brosna and on the Royal canal, 50 m. W. by N. of Dublin. Pop. (1901), 4500. It is a junction on the Midland Great Western railway where the branch for Longford, Sligo and Cavan leaves the main line. The principal churches are the parish church (1813) with tower and spire, and the Roman Catholic cathedral for the diocese of Meath. Tanning, brewing, and the manufacture of coarse woollens are carried on, and the town is the centre for the agricultural trade of the district. Mullingar was one of the ancient palatinate towns, but its present appearance is modern. It possessed an Augustinian convent founded in 1227, and a Franciscan monastery founded in 1239, but both were dissolved by Elizabeth. The town was the headquarters of William III before the siege of Athlone. It formerly returned two members to parliament, but was disfranchised at the Union in 1800. Mullingar is a centre for the trout-fishing in the Westmeath loughs, being in proximity to Loughs Ennell and Owal.

**MULLION** (corrupted from “munion”); this is derived from Fr. *moignon*, stump), in architecture, the English term for the perpendicular pieces of stone, sometimes like columns, sometimes like slender piers, which divide the bays or lights of windows or screen work from each other; equivalents are Fr. *menou*, Ital. *regolo*, Ger. *Fensterposte*. H. Wedgwood (Diss. of Eng. Bysm.) points out that the mullion is “the stump of the division before it breaks out into the tracery of the window.” In all styles, in less important work, the mullions are often
MÜLLNER—MULTAN

simply plain chamfered, and more commonly have a flat hollow on each side. In larger buildings there is often a bead or bowtell on the edge, and often a single small column with a capital; these are more frequent in foreign work than in English. Instead of the bowtell they often finish with a sort of double ogee. As tracery grew richer, the windows were divided by a larger order of mullion, between which came a lesser or subordinate set of mullions which ran into each other.

MÜLLNER, AMANDUS GOTTFRIED AドルF (1774–1826). German dramatic poet, nephew of Gottfried August Bürger, (g.v.), was born at Langendorf near Weissenfels on the 18th of October 1774. After studying law at Leipzig he established himself as advocate at Weissenfels and made his début as an author with the novel Incest, oder der Schutzgeist von Avison (1799). He next wrote a few comedies for an amateur theatre in Weissenfels; these were followed by more pretentious pieces: Der angelsche Kater (1800) and Der Blitz (1814, publ. 1818), after French models. With his tragedies, however, Der neunundzwanzigste Februar (1812), and especially Die Schuld (1813; publ. 1816), Müllner became the representative of the so-called Schicksalsdramaturker, and for several years "fate-tragedies" on the model of Die Schuld dominated the German stage. His later plays, König Yungur (1817) and Die Albaneserin (1820), were less important. Notwithstanding his literary success, Müllner was still a "gifted" lawyer. He was a member of Hofrat; he also edited various journals, and had a reputation as a vigorous if somewhat acrimonious critic. He died at Weissenfels on the 11th of June 1820.

Müllner's Vernisschreiten appeared in 2 vols. (1824–1826); his Dramatische Werke in 8 vols. (1828; 2nd ed., 1832). In 1830 four supplementary volumes were published containing mainly criticism. See F. K. J. Schütz, Müllners Leben, Charakter und Götst (1830); J. Minor, Die Schicksalsdramaturfen in ihren Hauptstreitern (1883), and the same author's volume. "Das Schicksalsdramen", (1884), in Kürschner's Deutsche Nationalliteratur, vol. 151.

MULOCK, SIR WILLIAM (1843— ). Canadian statesman and jurist, was born at Bond Head, Ontario, on the 19th of January 1843, the son of T. H. Mulock, M.D. From 1882 to 1895 he was a prominent member of the Liberal party in the Federal house; postmaster-general from 1896 to 1905, and minister of labour from 1905 to 1909. He introduced many improvements into the Canadian postal service, and in 1898 in face of much opposition induced the Inter-Imperial Postal Conference to adopt the principle of penny postage within the British Empire. In 1905 he resigned office, and was appointed chief justice of the exchequer division of the High Court of the province of Ontario. From 1881 to 1900 he was vice-chancellor of the university of Toronto, and was largely responsible for the success of the movement leading to the federation between that body and the Victoria University (Methodist).

MULREADY, WILLIAM (1786–1863). English subject painter, was born at Ennis, Co. Clare, on the 30th of April 1786. When he was about five years old his father, a leather-breeches maker by trade, removed to London, where the son received a tolerable education, chiefly under Catholic priests. He was fond of reading, and fonder still of drawing. When eleven years old Mulready was employed by an artist named Graham as the model for a figure in his picture of "Solomon Blessed by his Father David." The painter's interest in the lad did much to confirm his artistic proclivities; and, having studied at home for two years, Mulready applied for advice to Banks the sculptor, who sent him to a drawing school and permitted him to work in his own studio. In 1800 he was admitted a student of the Academy, and two years later he gained the silver plate of the Society of Arts. About this time he was associated with John Varley, the eccentric water-colour painter and drawing-master, whom he assisted in the tuition of his pupils, who included Cox, Fielding, Linnell, William Hunt, and Turner of Oxford. At eighteen he married a sister of Varley's, and at twenty-four he was the father of four sons. The marriage was unhappy, and the pair separated before many years. He "tried his hand at everything," as he said, "from a miniature to a panorama." He painted portraits, taught drawing, and up till 1809 designed illustrations to a series of children's penny books. His first pictures were classical and religious subjects of no great merit, and the early works which he sent to the celebrated high manscapes, but he soon showed his special aptitude for genre-painting, and in 1809 produced the "Carpenter's Shop," and in 1811 the "Barber's Shop," pictures influenced by the example of Wilkie and the Dutch painters. In 1813 he exhibited his "Punch," a more original and spontaneous work, which brought the artist into notice, and two years later his "Idle Boys" procured his election as associate. Next year he received full academic honours, and the election was justified by the "Fight Interrupted" which he then exhibited. It was followed by the "Wolf and the Lamb" (1820), the "Convalescent" (1822), "Interior of an English Cottage" (1828), "Dogs of Two Minds" (1830), the "Seven Ages" (1838), and in 1839 and 1840 by the "Sonnet and First Love," two of the most perfect and poetical of the artist's works. In 1840 he designed an allegorically covered postal envelope (the "Mulready envelope," soon discontinued) for Rowland Hill, and a set of dinner-deckts, the designs for which were selected by his paintings of the "Whistonian Controversy" (1842), "Choosing the Wedding Gown" (1846), and "Sophia and Burchell Haymaking" (1849). His later works, like the "Bathers" (1849), "Mother teaching her Children" (1859), and the "Toy Seller" (1862), showed declining powers, mainly attributable to failing health. The last evening of his life was spent at a meeting of the Academy, of which, for nearly fifty years, he had been a most active and efficient member. He died of heart disease on the 7th of July 1863.

MULTAN, or MOOLZAN, a city, district and division of British India, in the Punjab. The city is 4 m. from the left bank of the Chenab, near the ancient confluence of the Ravi with that river. It has a station on the North-Western railway. PoP. (1901), 87,394. The city is enclosed on three sides by a wall, but open towards the south, where the dry bed of the old Ravi intervenes between the houses and Citadel. Large and irregular suburbs have grown up outside the wall since the annexation in 1849. Within the city proper, narrow and tortuous streets, often ending in culs de sac, fill almost the whole space; but one broad bazaar runs from end to end. The principal buildings include the shrines of two Mahommedan saints and the remains of an ancient Hindu temple. The cantonments form the head-quarters of a brigade in the 3rd division of the northern army. Multan has manufactures of carpets, silk and cotton goods, shoes, glazed pottery and enamelled work, and an annual horse fair. It is moreover one of the most important trade-centres in the Punjab. It is a station of the Church Missionary Society. The District of Multan occupies the lower angle of the Bari Doab, or tract between the Sutlej and the Chenab, with an extension across the Ravi. Area, 6,027 sq. m. The population in 1901 was 716,626, showing an increase of 11-7% in the preceding decade. The cultivated portion of the province is watered by the Ravi, the Chenab, and the Multan: crops are wheat, millets, pulse, oil-seeds, cotton and indigo. There are factories for ginning and pressing cotton. Indigo is made only by native processes. Irrigation is largely conducted by inundation channels from the boundary rivers, but the centre of the district is barren. The district is traversed by the main line of the North-Western railway from Lahore.

1 Some reproductions of his early efforts in this direction are given, along with details of his life, in a scarce volume for the young, entitled The Looking-Glass, written by William Godwin under the nom de plume of Theophilus Marchiffe, and published in 1805.
which crosses the Sutlej by the Empress Bridge opposite Bahanwalpur. It is also entered by the branch from Lyallpur to Khanewal junction, crossing the Ravi.

The early Arab geographers mention Multan as forming part of the kingdom of Sind, which was conquered for the caliphate by Mahommed bin Kasim in the middle of the 8th century. On the dismemberment of the Mogul Empire in the middle of the 18th century, Multan fell to the Afghans, who held it with difficulty against the Sikhs. At length, in 1818, Ranjit Singh after a long siege carried the capital by storm; and in 1821 he made over the administration of Multan with five neighbouring districts to Sawan Mal, who raised the province to a state of prosperity by excavating canals and inducing new inhabitants to settle. After the establishment of the council of regency of Lahore, difficulties arose between Mulraj, son and successor of Sawan Mal, and the British officials, which led to his rebellion, and culminated in the second war and the annexation of the whole of the Punjab. The city of Multan, after a stubborn defence, was carried by storm in January 1849. The district at once passed under direct British rule, and order was not disturbed even during the Mutiny.

The Division of Multan is the south-western division of the Punjab. It was abolished in 1884, but reconstituted in 1901. Its area is 29,516 sq. m. and its population in 1901 was 3,614,675. It includes the six districts of Mianwali, Jhang, Lyallpur, Multan, Muzaffargarh, and Dera Ghazi Khan.

MULTIPLEPOINDING, in Scots law, the technical term for a form of action by which conflicting claims to the same fund or property are determined. The action is brought either by the holder or by a claimant in his name. All who have any claims in the fund or property in question are ordered to appear and give in their claims; the court then prefers them according to their respective rights, and the holder of the fund or property in dispute on payment or delivery is absolved from any further claim in regard to it. It corresponds to the process of inter-pleader in English law.

MULTITUBERCULATA, a group of extinct mammals, mostly of small size, whose remains are met with in strata ranging from the Trias to the Eocene, both in Europe and in North America. They are mostly known by their lower jaws, and take their name from the fact that the grinding teeth (fig. 2. m. 1 and 2, and fig. 3. a. b. c.) bear two or three longitudinal rows of tubercles, or are provided with tubercles round the edges. From this feature these otherwise unknown animals are believed to be related to the existing egg-laying mammals (duck-billed platypus and spiny anteater), constituting the order Monotremata, and are therefore provisionally placed near that group. The largest representative of the Multituberculata is Polymastodon from the Lower Eocene of New Mexico; the same beds also yield the smaller Plagiaulax; while from corresponding strata at Rheims, in France, has been obtained the nearly allied Neoplagiaulax. The latter takes its name from its resemblance to Plagiaulax (figs. 1 and 2) from the Purbeck strata of Swang, Dorsetshire, which was one of the first-known members of the group. Allodon and Clenodon represent the group in the Cretaceous of North America; and the English Purbeck genus Bolodon, in which all the cheek-teeth are multituberculate, also belongs here. Stereognathus (fig. 3) is another English Upper Oolitic type. Single teeth from the Rhaetic of England and Wurttemberg described as Microlestes apparently indicate the earliest member of the group. A skull from the Upper Triassic Karoo beds of South Africa described as Tritylodon longiceps, which has multituberculate molar teeth, was also at first placed in this group, but has been subsequently regarded as a reptile, although Dr R. Broom considers that the original determination is correct. Possibly a fore-limb from the same formation described as Theriodus physlarcus indicates a similar or allied animal. Not improbably Tritylodon indicates a direct link between the multituberculate mammals and the anomodont reptiles of the Permian and Trias.

(R. L.)

MUMMERS, bands of men and women in medieval and later England and elsewhere, who, during periods of public festivity, particularly at Christmas, dressed in fantastic clothes and wearing masks or disguised as animals, serenaded the people outside their houses or joined in the revels within. In a more restricted sense the term is applied to the actors in the old English rural folk-plays of St George, &c. and "mumming" thus becomes a contemptuous synonym for any form of stage-playing. The origin of the word mummer (older spelling "mumner," Fr. momeur) is not satisfactorily explained; but the verb "to mum" means both to muffle and to be silent, and "mummer" apparently comes from one or both of these senses. Mumming seems to have been survival of the Roman custom of masquerading during the annual orgies of the Saturnalia. "The disguising and mummyng that is used in Christemas tyme," Langley writes in his synopsis of Polydore Virgil, "in the North partes came out of the feasts of Pallas, that were done with visars and painted visages, named Quinquatria of the Romaynes." Aubanus, writing of mumming in Germany, says that "in the Saturnalia there were frequent and luxurious feastings amongst friends, presents were mutually sent, and changes of dress made: that Christians have adopted the same customs, which continue to be used from the Nativity to the Epiphany: that exchanges of dress too, as of old among the Romans, are common, and neighbours by mutual invitation visit each other in the manner which the Germans call mummery." Christmas was the grand season for mumming in England. Some were disguised as bears, others as unicorns, or wore deer's hide and antler's or ram's horns. Mumling led to such outrages that Henry VIII. issued a proclamation declaring the wearing of a mask or disguise a misdemeanor. Stow gives an account of an elaborate mummerly held in 1377 by the London citizens to amuse the son of the Black Prince, then living at Kennington (Surrey, 1603, p. 97). In Scotland, where mumming still exists at Christmas, Hogmanay, New Year's Day and Haddiel Monday, mummers are called "guisards." They usually present on these four nights a rude drama called Galatian, which, in various versions, is common throughout the Lowlands of Scotland (see Chambers's Popular Rhymes, p. 170).

MUMMUS, LUCIUS (2nd century B.C.), surnamed Achaiacus, Roman statesman and general. Consul in 146 B.C. Mummus was appointed to take command of the Achaean War, and having obtained an easy victory over the incapable Diaeus, entered Corinth unopposed. All the men, women, and children were put to the sword, the statues, paintings and works of art were seized and shipped to Rome, and then the place was reduced to ashes. The apparently needless cruelty of Mummus in Corinth, by no means characteristic of him, is explained by Mommens as due to the instructions of the senate, prompted by the mercantile party, which was eager to get rid of a dangerous commercial rival. According to Polybius, his inability to resist the pressure
of those around him was responsible for it. In the subsequent settlement of affairs, Mummius exhibited considerable administrative powers and a high degree of justice and integrity, which gained him the respect of the inhabitants. He specially abstained from offending their religious susceptibilities. On his return to Rome he was honoured with a triumph. In 142 he was censor with the younger Scipio Africanus, whose severity frequently brought him into collision with his more lenient colleague. Mummius was the first *novus homo* of plebeian origin who received a distinctive cognomen for military services. His indifference to works of art and ignorance of their value is shown by his well-known remark to those who contracted for the shipment of the treasures of Corinth to Rome, that "if they lost or damaged them, they would have to replace them." For the theatrical pageants exhibited by him he erected a theatre with improved acoustical conditions and seats after the Greek model, thus marking a distinct advance in the construction of places of entertainment.

His brother, Spurius Mummius, a man of greater refinement and intellectual powers, accompanied Lucius as his legate to Achaean, whence he sent letters to his friends at Rome, describing his experiences in humorous verse. These letters, which were still kept alive by ability to make jests, were the first example of a distinct class of Roman poetry—the poetic epistle. Both he and his brother are alluded to by Cicero as mediocre orators, whose style was simple and old-fashioned, although Lucius, as a Stoic, was more concise.

**Mummy** (from the Persian *mamai*, pitch or asphalt), a dead body, as preserved by the ancient Egyptian method of embalming. The preservative climate of Upper Egypt and the belief of the Egyptians in life after death must be the causes which led them to take unusual care for preserving the bodies of their dead. In prehistoric times in Egypt the dead were laid in the graves on mats in the crouching position common in the burials of primitive peoples, and were supplied with jars of food, flint instruments, &c. Perhaps the attempt was already made to preserve the bodies by drying or otherwise. In a few instances, such bodies, probably more than five thousand years old, have been found with skin and hair well preserved though dried and shrunk; usually everything but the bones has decayed. With the advent of the Dynasties the body was sometimes of the principal people, and lying extended at full length. By the time of the VIth Dynasty it was usual to lay the corpse on its left side in the attitude of sleep, and a wooden coffin was often provided upon which were inscribed magic formulæ that had already been employed for ages in ritual. In the Middle Kingdom necropolis of Beni Hasan, Garstang found many intact interments in coffins, and in one case the body was well preserved. Several were accompanied by boxes divided into four compartments and inscribed with the names of the four deities who represented the internal organs of the body. This indicates that the custom of taking out these organs and wrapping them separately was already in vogue in the most lavish form of burial. But the parcels, examined by an expert, contained no trace of organic remains, proving how much the Egyptians depended on magic imitations and make-believe. It was not until the New Kingdom that the processes of embalming reached a high degree of elaboration. Later still, in the last millennium B.C., it seems that even the bodies of the poor were pickled. The embalmers were accustomed to keep the corpse in all for seventy days before burial (cf. Gen. 1. 1; Hebrew 860) to be scaled, wrapped in linen bandages, and put in the coffin. This is confirmed by the monuments as far back as the age of Rameses II. (c. 1300 B.C.) and may be conjectured to have been established still earlier.

The Egyptians did not stop at the mummification of the human body; sacred animals, birds, reptiles, fishes, and even insects were treated in a similar way, and the meat offerings deposited with the wealthy dead were likewise "preserved." Vast cemeteries of animals which belonged to the revered species have been discovered; more especially may be mentioned that of the cats at Bubastis, the remains of which, charred by some great fire, until recently filled numberless chambers of crude brick in the ruins at Zagaazig. In the hawk cemeteries birds and pickled and buried in long bundles, forming sometimes an assortment that is not without incongruities from the naturalist’s point of view. From a few of these bundles may be extracted not only numbers of raptorial birds, large and small, including owls, but also the hawk-like cuckoo, the shrike, and even the swallow. The larger animals were represented in mummies by the head and a selection of the bones. Bones of bulls and male calves, especially crania, were collected and formed into huge ox-like mummies.

What the Egyptians really thought of mummification can only be partially guessed. Custom, changing in some degree from century to century, governed their practice, and no doubt was regulated by the priests. At first the luxury of mummification was reserved for the king, who was identified with Osiris and was buried with an abundance of ritual and magic words. But the king required his courtiers, and his courtiers in turn needed their servants in permanent attendance. Partly in consequence of this, the deification of the king, with all its concomitants, was gradually extended through the ranks of the noble and wealthy until it came within the reach of the humblest, and the spells of deification after death. Finally, in a papyrus of the Roman age the word "god" is practically defined as "buried," i.e. with due rites. Beliefs regarding the gods and life after death were self-contradictory and variable, but none interfered with the custom of preserving the body. It was always the prayer that the soul (bat) should be able to revisit the corpse (bkat), and some inscriptions show an expectation of the body itself being revivified, "the mouth speaking," "the legs walking," and everything conforming with its previous terrestrial life. At the same time the ko ("life," "activity," and almost "ghost," which clung to the neighbourhood of the tomb and enjoyed the ghosts of offerings in ghostly fashion, had some of the independent enterprise which the bai possessed in abundance. The mummified corpse as a divine thing—probably the mere bkat—was called the suhu (an old word meaning "noble") or ikh, which in the latter period meant a spirit or demon. As the corpse was found generally to disappear and decay in spite of preservative magic, especially in the early ages, various substitutes were resorted to; statues were formed of wax, straw, and bread, and was made from the costliness, even these were subject to decay or destruction by violence, and in the absence of anything more substantial the Egyptians doubtless reflected that magic words alone in the last resort made everything right.

Under the Old Kingdom the attendance on and services for a dead man—the sacrifices and libations at his tomb—were left, together with endowments, to a staff of priests, called "servants of the ko(ka)," whose offices were hereditary. This system led to disputes and neglect, and was so unworkable that we find in the texts of the Middle Kingdom the whole responsibility put upon one well-endowed "ko-servant," who passed on his office to a single heir. How these things were managed during the New Kingdom we do not know. In the last thousand years B.C. the life of the Egyptians consisted largely in every kind of religious and superstitious observances. Papyri of the Ptolemaic age or somewhat earlier afford much information about the people of the necropolis. In this age the *chochoyae*, as the Greeks called them ("libation priests," or "holy men"), belonged to an inferior grade of the priesthood, equivalent to the *pastophori* of the deities, and were organized in guilds for the different cemeteries. A single chochoye would have an interest, not always the sole interest, in a large number of mummies, and these interests could be disposed of by will or contract, bought and sold. The *tirachiuce*, or embalmers, had no permanent interest in the mummies they prepared.

Thanks to the great care expended on the preservation of the royal dead, although the mummies of all the other kings have disappeared, a wonderful series of the Theban kings and queens of the New Kingdom from the XVIIIth Dynasty to the XXIst
MUMPS

Dynasty has come down to us. It comprises some of the most notable figures in Egyptian history—Ahmosi (Amasis) I., who freed Egypt from the Hyksos, Tethmosis I. and III., the conquerors of Semitic and masters of the empire, Amenophis III., the great builder, whose likeness is preserved in the colossi of Memnon, probably also his son, Amenophis IV. (Akhenaton), the heretic king, and Seti (Sethos) I. and his son Rameses II. The mummy of Seti I. is in the finest possible preservation, but others, after being brutally plundered, were rewrapped by the piety of later generations.

In Lower Egypt practically all the mummies have perished; but in Upper Egypt, as they were put out of reach of the inundation, the cemeteries, in spite of rifling and burning, yield immense numbers of preserved bodies and skeletons; attention has from time to time been directed to the scientific examination of these in order to ascertain race, cause of death, traces of accident or disease, and the surgical or medical processes which they had undergone during life, &c. This department of research has been greatly developed by Dr Elliott Smith in Cairo. He has examined not only the more recently found of the royal mummies, but also multitudes of skeletons, &c., which have been brought from the official excavations of the government and from other work. His researches, in particular instances, prove their high importance for the history of disease, for characterization of the races inhabiting Egypt, and in other ways. The cemeteries just south of the First Cataract on a first examination reveal a prehistoric race of Egyptian type, a group of male negro mercenaries, a group of male prisoners executed by hanging during the New Kingdom, while from a necropolis of Christian foreigners of about the 6th century comes the first instance of gout in an ancient body from Egypt. Among the prehistoric people are many female skeletons with a fractured right ulna sustained in warding off blows, and some of these women had died while still wearing splints. Circumcision is traceable on all the male bodies which are in a state to show its effects. The royal mummies furnish evidence of age at death as well as of health and physical character. A series of forty-four mummies of priests and priestesses of the XXIst Dynasty furnished the material for an important monograph. Earlier, the processes of mummification produced a skeleton merely clothed in a dry and shrunken skin. At this time, however, the flesh was replaced by a stuffings of sawdust, sand, or other lasting material, introduced with great skill through a few incisions and apertures, so that the natural forms were completely restored. The heart was left in place, but the liver, lungs, stomach and intestines were pickled and wrapped separately and then restored to the body cavity. Later, the form was reproduced by elaborate external wrappings of the different parts of the body before the final swathing; later still, in the Ptolemaic age, by coarse padding with plenty of linen and pitch. The XXIst Dynasty marks the highest level of the art. The Christians of the early centuries, looking for corporeal resurrection, avoided the incisions, extraction of organs, &c., practised by their pagan forefathers, and buried the body entire after pickling it in salt. Their stricter leaders, however, objected to a custom which so easily led to the worship of relics and the continuance of pagan observances; and with the advent of Islam embalming fell into disuse.

Outside Egypt mummification was practised amongst the ancient Peruvians, who took advantage of the desiccating atmosphere and salt soil of their caves for preserving the dead in good condition without any embalming process. Among the Guanches of the Canary Islands, however, the Egyptian methods of emptying the body and padding he skin were closely paralleled.

A word may be added about the use of mummy in medicine. The name, as has been pointed out above, is derived from the Persian mumiāt, meaning pitch or asphalt, which substance occurs frequently in the prescriptions of the Greek and Roman medical writers. Medieval physicians in the East conceived the happy idea that the highest virtue would exist in that which had been already employed by the Egyptian priests in preserving the human body. Thus the bituminous and fatty matters found about the mummies and their wrappings were employed as a sovereign remedy, particularly for wounds and contusions, and a brisk trade began in these "exudations" of mummies. This led further to the medicinal use of fragments of the mummies themselves; and, finally, the starting-point was lost sight of, so that the dried or prepared flesh of criminals became one of the standard forms of mummy in the pharmacopoeia. It was not till the 18th century that the importance of mummy in all its forms waned, and in some of the least progressive quarters of central Europe it survived even to the middle of the 19th.

Elliott Smith, A Contribution to the Study of Mummification in Egypt (Cairo, 1906); The Archaeological Survey of Nubia Bulletins (Cairo, 1908 seq.); Dr Lortet and M. C. Gaillard, La Faune momifique de l’ancienne Egypte (Lyons, 1898); A. Wiedemann, "Mumie als Heilmittel," in Zeitschrift des Vereins für rheinische und westfälische Volkskunde (1906).

MUMPS (syn. Cynanche parotidacea, parotitis; also, "The Branks"), a specific infectious disease characterized by inflammatory swelling of the parotid and other salivary glands, frequently occurring as an epidemic, and affecting mostly young persons. The name "mumps" (O. Eng. "to mump," meaning to suck) originated, no doubt, in the patient’s appearance. The disease generally sets in with symptoms of a cold or catarrh accompanied with slight febrile disturbance; but soon the nature of the ailment is announced by the occurrence of swelling and stiffening in the region of the parotid gland in front of the ear. The swelling speedily increases in size and spreads downwards towards the neck and under the jaw, involving the lacrimal glands in that locality. The effect is to produce much disfigurement, which becomes still greater should the inflammation spread, as often happens, to the glands on the other side of the face and neck. Pain is present in the swollen parts, but it is seldom severe, nor is there much redness or any tendency to suppuration. There is, however, considerable interference with the acts of mastication and swallowing. After continuing for four or five days the swelling and other symptoms abate, and the parts are soon restored to their normal condition. During the period of convalescence there occasionally occur some swelling and tenderness in other glands, such as the testicles in males (orchitis), and the mammae or ovaries (ophtheritis) in females, and possibly involvement of the pancreas, but these are of short duration and usually of no serious significance. Mumps is in general a mild disease, and requires little treatment beyond a gentle laxative, the application of warm fomentations to the swollen and painful parts, the use of soft food, and rest.
